REVISION HISTORY

Revision	Date	Description
1.0	01/2023	Initial Release
1.1	04/2023	Updated for Firmware 1.8
1.2	06/2023	Updated for Firmware 1.9

1 CORRECTION ALGORITHM OVERVIEW

The TMx00 supports three correction algorithms to compensate for temperature and voltage non-idealities:

1. **Lookup Table** – Temperature correction algorithm
2. **Temperature Polynomial Curve Fit** – Temperature correction algorithm
3. **Supply Voltage Curve Fit** – Voltage correction algorithm

The TMx00 correction algorithms use integer numbers (digital codes) that represent temperatures and voltages to make compensation adjustments. The ADC converts analog signals into the digital domain for the MCU to calculate the appropriate Correction DAC input code and produce an analog correction voltage.

The first two algorithms use a *Temp Code* input to generate a *CorrDAC Code* from the Correction DAC output to correct frequency variations over temperature. Only one of the temperature correction algorithms may be used during operation.

The *Temp Code* value is an integer with the range of 0 to 4095 and corresponds to the temperature being measured and digitized through the ADC. A -40C to 90C temperature range will utilize a *Temp Code* range of approximately 2000 to 3200. The *Temp Code* is produced from either the IC internal temperature sensor or an external thermistor (via the THRM pin).

The *CorrDAC Code* value is an integer with the range of 0 to 4095 and corresponds to the DAC input code needed to vary the capacitance across an external varactor or the internal TMx00 Varicap to correct the frequency variation for a given temperature.

The *CorrDAC Voltage* is resulting Correction DAC output voltage for a given *CorrDAC Code*. It is calculated by multiplying the Correction DAC's reference voltage by the ratio of the *CorrDAC Code* to the Correction DAC's full-scale code (4095).

$$\text{CorrDAC Voltage} = \frac{\text{CorrDAC Code}}{4095} * \text{BYPASS Pin Voltage}$$

As a brief relationship example, a measured temperature of 25C may produce a *Temp Code* of 2541 and results in a *CorrDAC Code* of 1983 and a *CorrDAC Voltage* of 1.4043V for the correct center frequency of a unique TCXO assembly.

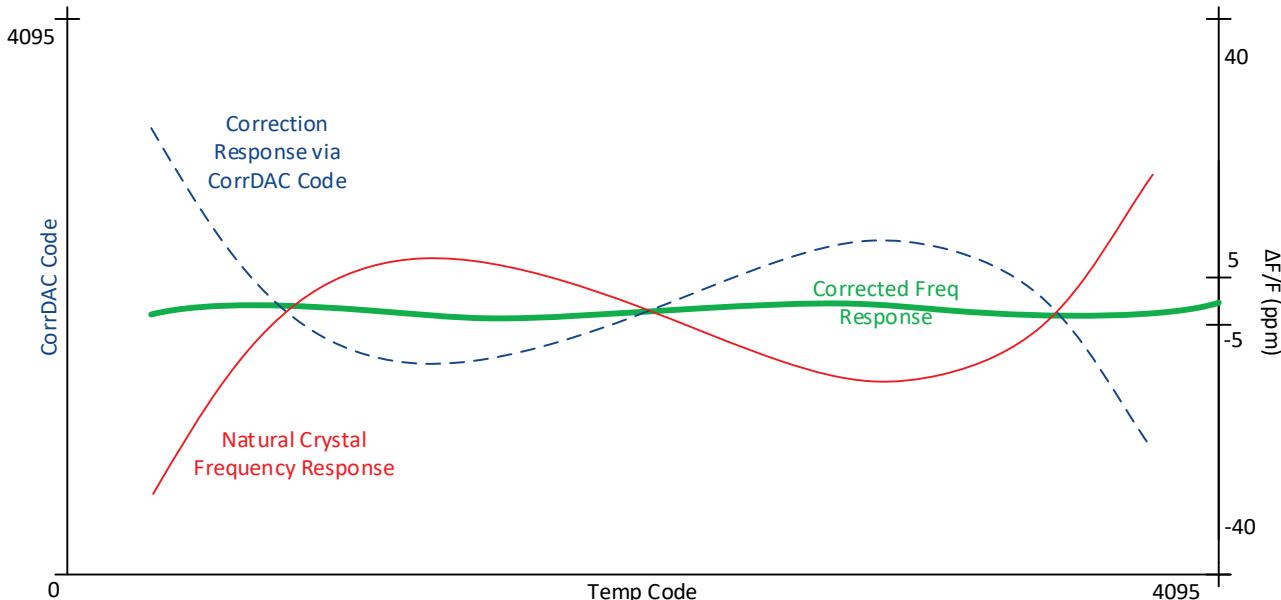

Figure 1 Temp Code and CorrDAC Code Relationship

Adjustable Timing Parameters

The TMx00 correction mechanism is a hybrid analog/digital implementation and has several adjustable timing parameters that allow customers to tune timing modules to the time constants of the intended applications. The adjustments also implement low pass filters to reduce crystal adjustment transients.

Supported adjustable timing parameters include:

Temperature Sample Interval – This sets the time interval (in ms) for measuring the temperature sensor and VDDA value. The interval is between 20ms and 2550ms. Both the temperature and VDDA readings are averaged over 8 sample intervals, updated at each sample interval (rolling average).

Frequency Correction Interval - This sets the time interval (in ms) for updating the Correction DAC value applied to the Varicap or external varactor. The interval is between 20ms and 2550ms.

Averaging Intervals - This sets the number of Frequency Correction Intervals used to calculate an average DAC correction value, updated each correction interval (rolling average). The averaging is between 1 and 16.

Lookup Table Curve Fit

The Lookup Table correction technique uses the measured reading from the IC temperature sensor or external thermistor (*Temp Code*) and generates a *CorrDAC Code* via a lookup table.

The lookup table is arranged from the lowest *Temp Code* to the highest *Temp Code* with up to 80 defined points. The spacing between the points is user defined to account for changing crystal temperature coefficient slopes. The appropriate DAC correction code (*CorrDac Code*) between the defined *Temp Code* points is calculated by linear interpolation.

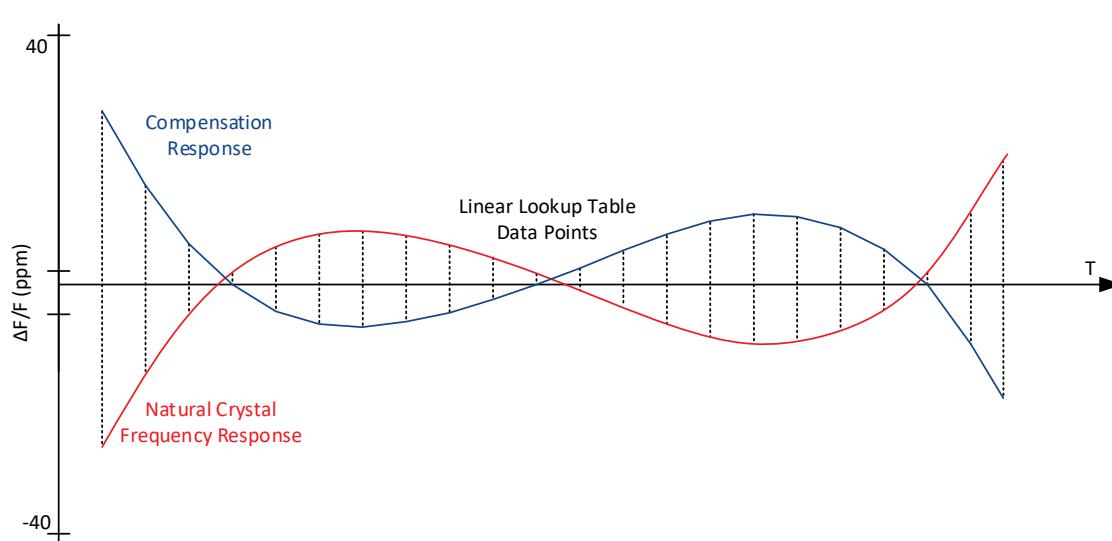

Figure 2 Linear Lookup Table Concept

Temperature Correction Polynomial Curve Fit

The temperature polynomial curve fit correction technique uses the measured temperature reading from the IC sensor or external thermistor (*Temp Code*) and calculates a *CorrDAC Voltage* via polynomial curve fit using the correction order coefficients, $a_0 - a_9$.

The correction process computes the Correction DAC voltage needed for best correction. The *CorrDAC Voltage* range is from 0V up the voltage of the BYPASS pin (typically, 2.9V or 3.3V depending on configuration). The correction value is converted into a 12-bit DAC input digital code (*CorrDAC Code*), 0 for 0V, and 4095 for the max BYPASS Voltage. The internal tuning Varicap operates over a range of 0V to 2.9V, so the *CorrDAC Voltage* needs to be limited when BYPASS is operated from a supply greater than 2.9V.

$$\text{Corr}_{\text{temp}}(x) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 + a_9x^9$$

$x = \text{TempCodeNormalized}$: *TempCode normalized for Mean and Standard Deviation*

$$\text{Corr}_{\text{temp}}(x) = \text{CorrDAC Voltage} = \text{Correction DAC voltage}$$

To use the polynomial curve fit algorithm, the following data needs to be selected or entered:

1. Desired correction order: For some applications 3rd or 5th order corrections may produce better results over temperature than a 7th or 9th order correction. This item can be set as needed for each oscillator application.
2. *Temp Code* Mean and *Temp Code* Std Dev: Measure the module over temperature and capture the *Temp Code* for each measured temperature point. Compute the mean and standard deviation of the *Temp Code* values. Then scale the *Temp Code* values by the mean and standard deviation generating x (*Temp Code Normalized*) for the above equation.
3. CorrDAC Codes over Temperature: As part of the module measurements over temperature, determine the *CorrDAC Code* that produces the least error. Convert the *CorrDAC Code* to *CorrDAC Voltage* by scaling it, 0 to 4095 for the voltage range 0 to the BYPASS pin Voltage. *CorrDAC Voltage* is $\text{Corr}_{\text{temp}}(x)$ in the equation above.
4. Use polynomial curve fit software to find the values of a_0 to a_n based on x and $\text{Corr}_{\text{temp}}(x)$.
5. Enter the coefficients, $a_0 - a_9$, the *Temp Code* mean, and the *Temp Code* Std Dev for the respective correction order. The coefficients are single precision floating point numbers stored in the microcontroller. Single precision floating point numbers have 7-8 decimal digits of precision and ensure that all significant digits are entered into the microcontroller.

Supply Voltage Curve Fit

The *CorrDAC Voltage* values are not overly sensitive to supply voltage (VDDA) variation when the internal BYPASS regulator is enabled. The *Temp Code Normalized* values have some dependency on supply voltage. This means that supply voltage variations will shift the *Temp Code* values. The supply voltage polynomial curve fit correction techniques are optional enhanced correction methods that generate adjustment terms to account for this shift.

A *Corr_{voltage}* term corrects for frequency shifts over supply voltage variation and uses the coefficients, $b_1 - b_3$.

A *Corr_{voltage_temp}* term corrects for frequency shifts from cross correlated supply voltage and temperature variation and uses the coefficients, $c_1 - c_3$.

The user selects whether these correction terms are applied to either the *Temp Code* or *CorrDAC Code* depending on the architecture and sensitivity of supply voltage movement of the TCXO module. Each choice has further options regarding the order of correction desired.

Temp Code Adjustment Option

Because the supply voltage range of the TMx00 is $\pm 5\%$, the standard deviation of the *VDDA Code* range is set internally with respect to the nominal *VDDA Code*.

$$VDDA_{SD} = \text{Standard deviation of VDDA}$$

The Standard Deviation is defined so a 5% high supply voltage gives a $VDDA_{SD}$ (or σ) of +3.0, and a 5% low supply gives a $VDDA_{SD}$ of -3.0.

$$VDDA_{SD} = VDDACode_{NOM} \left(\frac{0.05}{3} \right)$$

$VDDACode_{NOM}$ is the ADC code value measured by the IC when the VDDA supply voltage is 3.3V. A typical ADC code value is 2330. Note that the VDDA ADC input is divided by 2, so the 2330 code represents an input value of 1.65V.

$$\Delta VDDA = \frac{VDDACode_{Meas} - VDDACode_{Nom}}{VDDA_{SD}}$$

Applying the correction by adjusting the *TempCode*:

$$Temp_{ADJ} = TempCodeNormalized + \Delta TempCode(\Delta VDDA)$$

Where:

$Temp_{ADJ}$ is the new *TempCodeNormalized* value input into the main $Corr_{temp}(x)$ function for frequency correction

$\Delta TempCode$ is the *Temp Code* adjustment based on voltage and temperature measurements

Temp Code Corr_{voltage} 1st Order Correction Option

$$\Delta TempCode(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA)$$

Temp Code Corr_{voltage} 3rd Order Correction Option

$$\Delta TempCode(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3$$

Temp Code Corr_{voltage} & Corr_{voltage temp} 3rd Order Correction Option

$$\begin{aligned} \Delta TempCode(\Delta VDDA) &= Corr_{voltage}(\Delta VDDA) + Corr_{voltage_temp}(\Delta VDDA) \\ &= b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3 + c_1(\Delta VDDA)(TempCode) \\ &\quad + c_2(\Delta VDDA)^2(TempCode) + c_3(\Delta VDDA)(TempCode)^2 \end{aligned}$$

CorrDAC Code Adjustment Option

Applying the correction by adjusting the *CorrDAC Code*:

$$\text{CorrDAC}_{\text{ADJ}} = \text{CorrDAC Code} + \Delta\text{CorrDAC Code}(\Delta VDDA) \text{ - when using the Lookup Table Correction}$$

Or

$$\text{CorrDAC}_{\text{ADJ}} = \text{CorrDAC Voltage} + \Delta\text{CorrDAC Voltage}(\Delta VDDA) \text{ - when using the Polynomial Correction}$$

Where:

$\text{CorrDAC}_{\text{ADJ}}$ is the new *CorrDAC Code* value output for frequency correction (Lookup Table Correction)

$\Delta\text{CorrDAC Voltage}$ is the new *CorrDAC Voltage* output for frequency correction (Polynomial Correction)

$\Delta\text{CorrDAC Code}$ is the *CorrDAC Code/Voltage* adjustment based on voltage and temperature measurements.

CorrDAC Code Corr_{voltage} 1st Order Correction Option

$$\Delta\text{CorrDAC Code}(\Delta VDDA) = \text{Corr}_{\text{voltage}}(\Delta VDDA) = b_1(\Delta VDDA)$$

CorrDAC Code Corr_{voltage} 3rd Order Correction Option

$$\Delta\text{CorrDAC Code}(\Delta VDDA) = \text{Corr}_{\text{voltage}}(\Delta VDDA) = b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3$$

CorrDAC Code Corr_{voltage} & Corr_{voltage temp} 3rd Order Correction Option

$$\Delta\text{CorrDAC Code}(\Delta VDDA) = \text{Corr}_{\text{voltage}}(\Delta VDDA) + \text{Corr}_{\text{voltage temp}}(\Delta VDDA) = b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3 + c_1(\Delta VDDA)(\text{TempCode}) + c_2(\Delta VDDA)^2(\text{TempCode}) + c_3(\Delta VDDA)(\text{TempCode})^2$$

2 CORRECTION ALGORITHM DEVELOPMENT FLOW

Developing the correction algorithms on the TMx00 is described in four sections:

1. **Main Flow** – High level overview flow of entire development process
2. **Temperature Data Collection Flow** – Details into the data collection performed at each temperature step
3. **Voltage Data Collection Flow** – Details into the data collection performed at each supply voltage step
4. **Correction Implementation Flows** – Details into processing the data required for each correction technique and calculating the needed parameters.

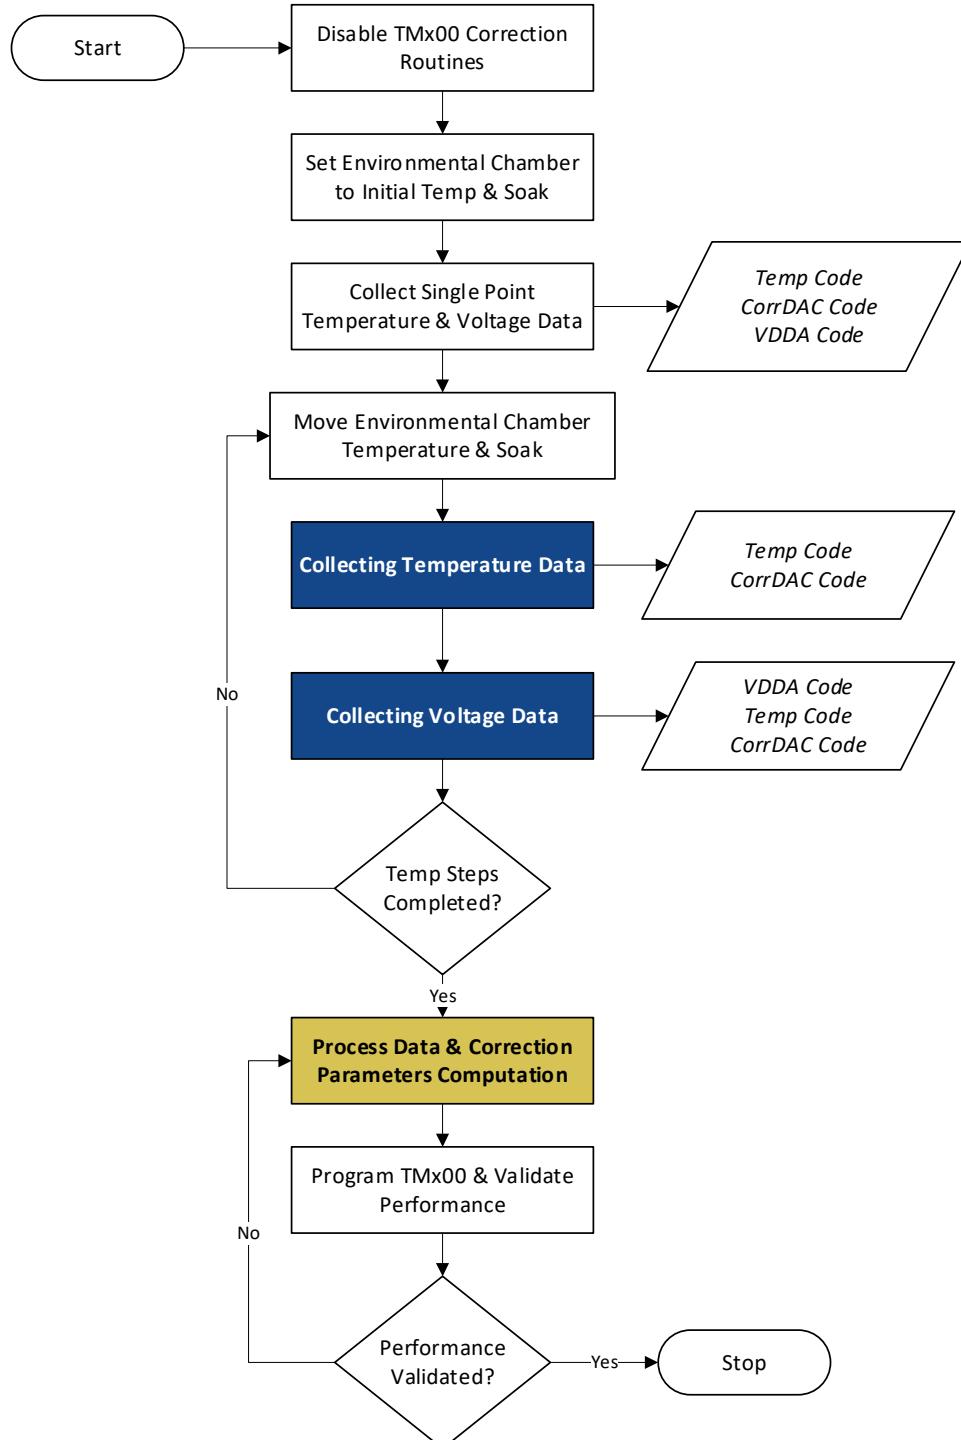

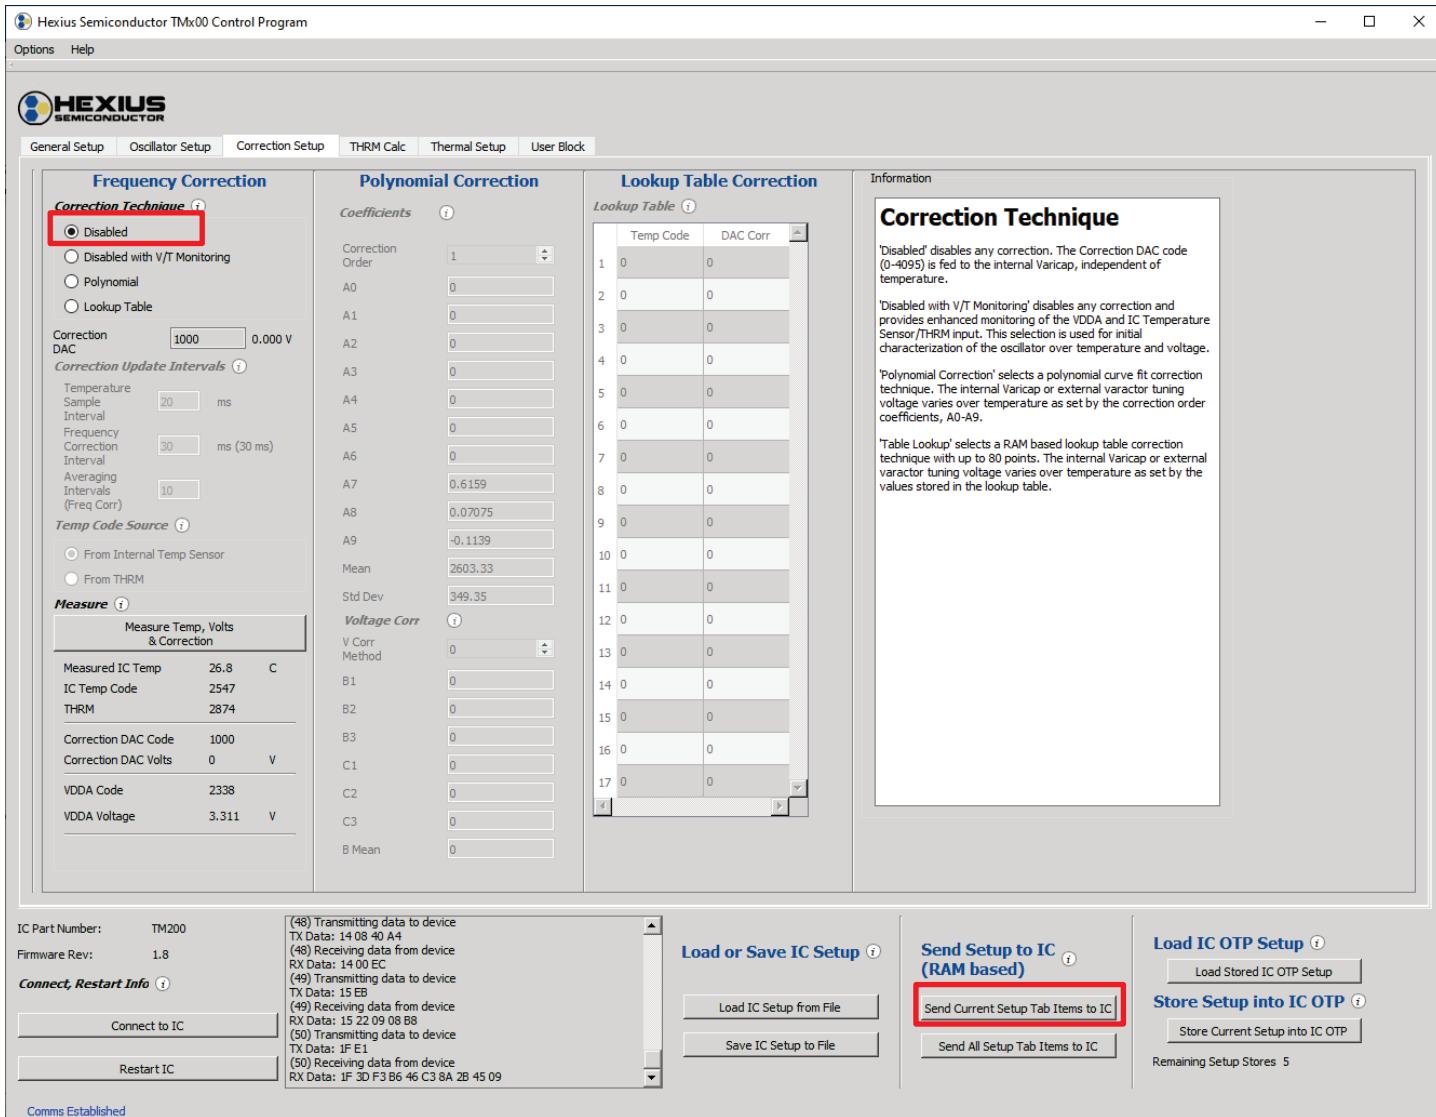

Figure 3 Main Flow for Correction Algorithm Development

Disable TMx00 Correction

Select the ‘Disabled’ Correction Technique and send the configuration to the IC by pressing the ‘Send Current Setup Tab Items to IC.’ If the Correction Technique is not disabled, the IC correction algorithm will be active and interfere with data collection.

I²C Command Option

Instead of using the TMx00 Control Software, the TMx00 correction routines are disabled by writing into the corr_order RAM setup location with following I²C commands (See the *TMx00 Programming Reference Manual* for more information):

Send: 0x19, 0x20, 0x00, 0x01, 0x00, 0xC6

Recv: 0x19, 0x00, 0xE7

Set the corr_b0 term to 0.0 ensuring no voltage trim adjustments. Since this is a floating-point value, write four bytes.

Send: 0x19, 0xE0, 0x00, 0x04, 0x00, 0x00, 0x00, 0x00, 0x03

Recv: 0x19, 0x00, 0xE7

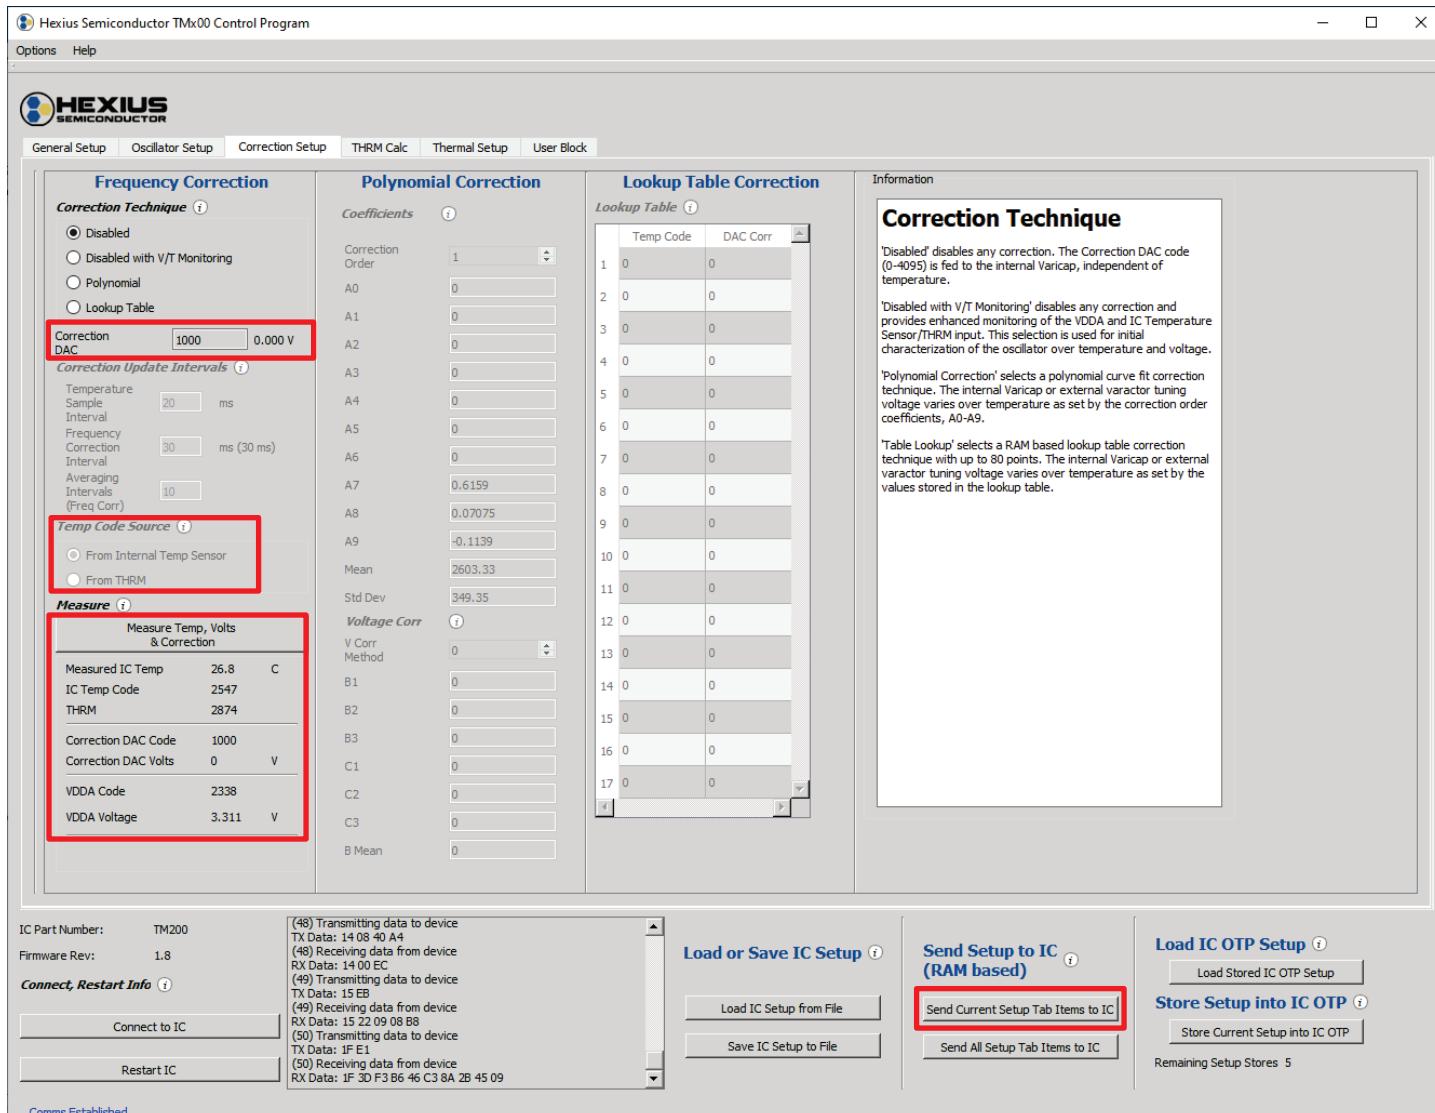

Set Environmental Chamber to Initial Temperature

Set the environmental chamber to the desired initial temperature and soak as appropriate.

Collecting Single Point Temperature Data

The temperature measurement can be sourced from the internal temperature sensor of the IC (which is a measurement of the IC temperature) or from an external thermistor through the THRM pin of the IC. Select which source to collect the *Temp Code* data from. The internal temperature sensor is the default configuration since it requires no additional external components or setup. Send the configuration to the IC by pressing the ‘Send Current Setup Tab Items to IC.’

The Correction DAC input window allows the user to manually enter a *CorrDAC Code* (0 to 4095) and send the value to the IC by pressing the ‘Send Current Setup Tab Items to IC’ to set the desired frequency. The user can also retrieve the *Temp Code* and *VDDA Code* along with other measured/converted data by pressing the ‘Measure Temp, Volts & Correction’ button.

Collecting Temperature Data over a wide temperature range is a process detailed in the next flow diagram. This involves obtaining the detailed *Temp Code*, the *CorrDAC Code*, and if desired, the *VDDA Code* data needed for full correction implementation over the desired temperature range.

Step Environmental Chamber Through Temperature Range

Move the environmental chamber through the desired temperature range and step size with the appropriate soak time. At each temperature point, collect the temperature data detailed in the Temperature Data Collection Flow section.

Process Data Determine Correction Parameters

Processing the temperature data is a procedure detailed separately in the Correction Implementation Flow sections. This involves evaluating the collected temperature data points and generating the information needed by the TMx00 for implementing the desired correction techniques.

Program the TMx00 & Validation

Once the correction parameters have been determined from processing the temperature data, the TMx00 is programmed with the parameters for the correction technique that is to be used and validated with the resulting parameters. The correction technique and parameters can first be validated with the RAM based storage without having to send the data into the OTP storage. Select the desired correction technique, enter the correction values, and send the setup to the IC. The oscillator can be cycled over temperature and voltage as needed for testing. Correction values can be updated as many times as needed until the final values have been determined.

Storing Values in the OTP Setup Block

After the corrections are validated, the desired setup should be programmed into the TMx00 OTP as part of the oscillator setup. The values in the OTP will be used at each power-up once they are programmed. The TMx00 supports multiple OTP writes by providing 6 incremental storage blocks. If the contents of the OTP need to be changed, the new parameters are stored in the next storage block and the TMx00 increments a pointer to read from the new storage block upon startup. The process of writing an OTP storage block is defined in *TMx00 Programming Reference Manual* or can be accomplished through the TMx00 Control Software.

Information

Correction Technique

'Disabled' disables any correction. The Correction DAC code (0-4095) is fed to the internal Varicap, independent of temperature.

'Disabled with V/T Monitoring' disables any correction and provides enhanced monitoring of the VDDA and IC Temperature Sensor/THRM input. This selection is used for initial characterization of the oscillator over temperature and voltage.

'Polynomial Correction' selects a polynomial curve fit correction technique. The internal Varicap or external varactor tuning voltage varies over temperature as set by the correction order coefficients, A0-A9.

'Table Lookup' selects a RAM based lookup table correction technique with up to 80 points. The internal Varicap or external varactor tuning voltage varies over temperature as set by the values stored in the lookup table.

3 TEMPERATURE DATA COLLECTION FLOW

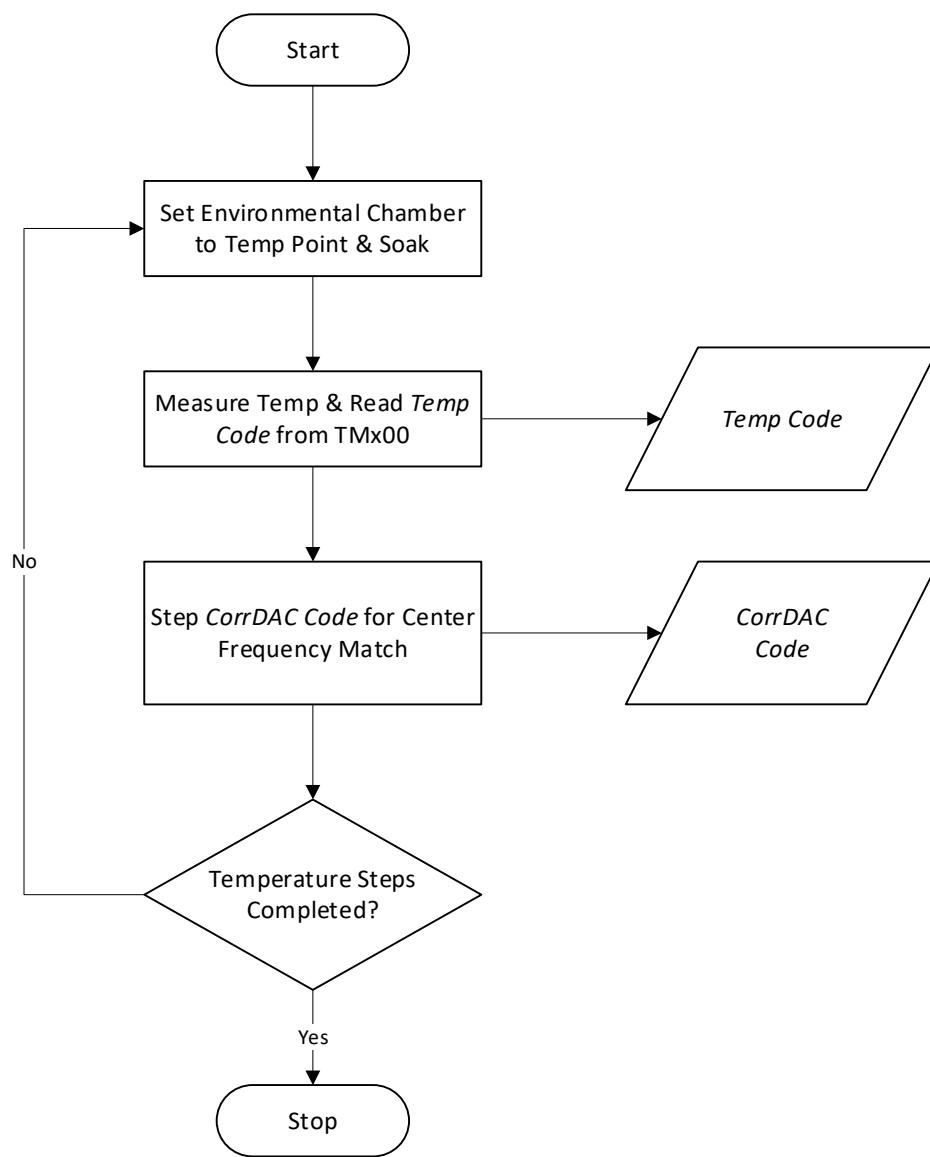

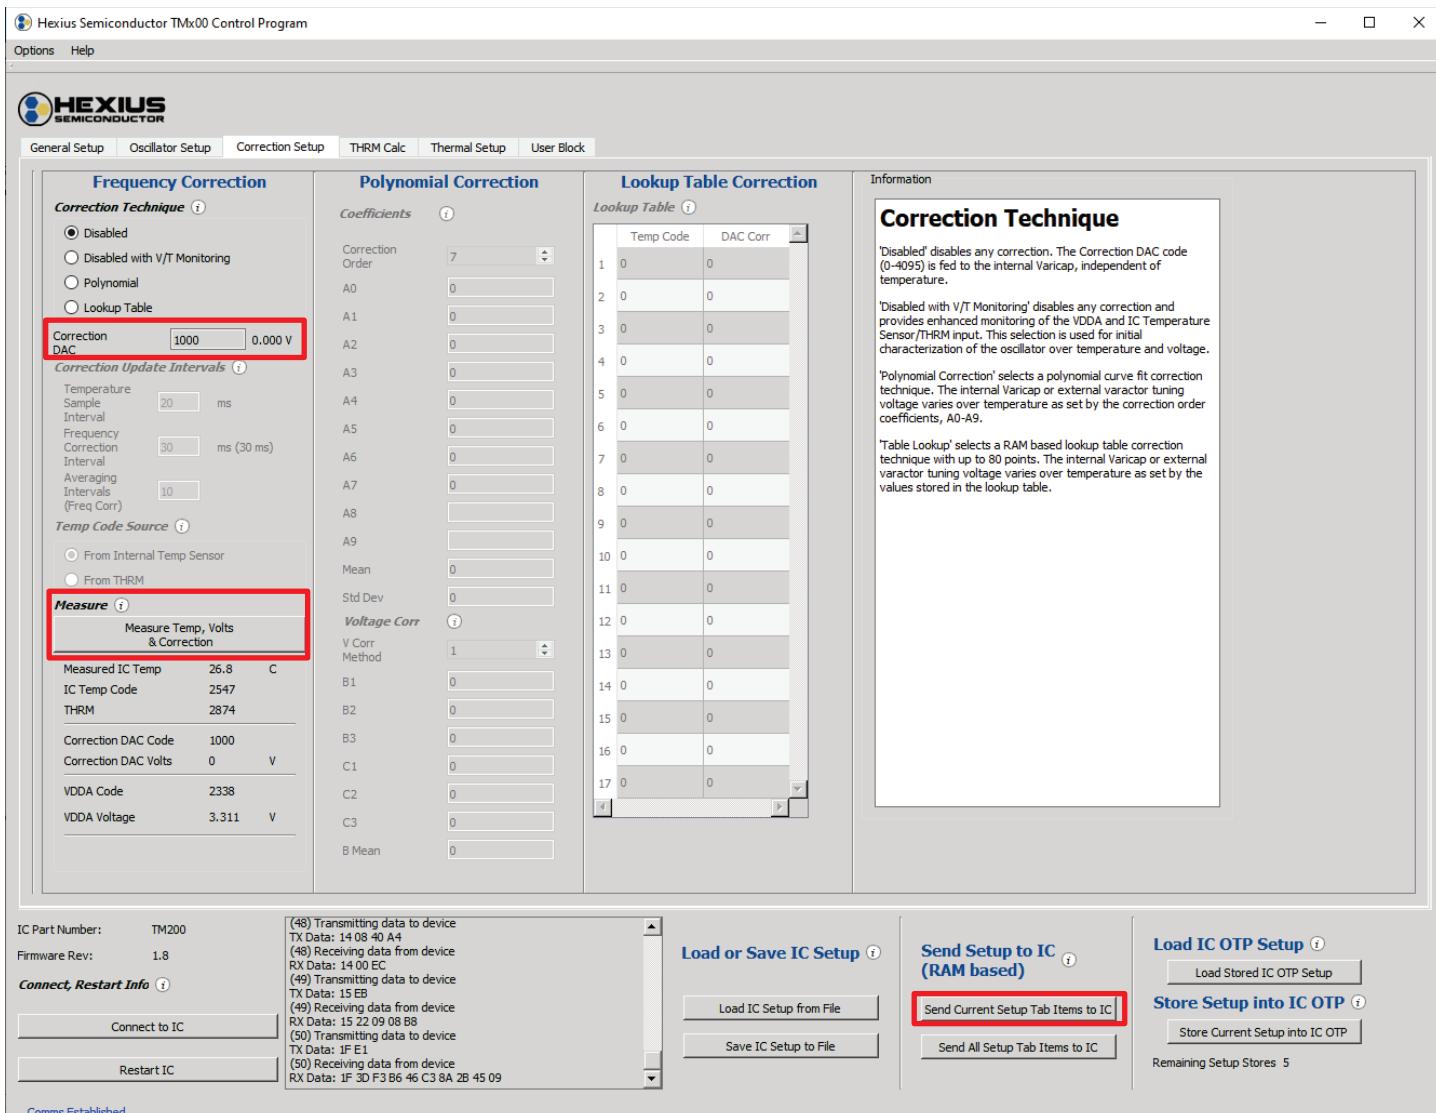

Figure 4 Temperature Data Collection Flow

Set Environmental Chamber to Starting Temperature Point

Set the environmental chamber to the desired starting point for the temperature sweep and soak as appropriate. The number of data points and step size in the temperature sweep will be dependent on the crystal characteristics and desired accuracy.

Measure Temperature & Read Temp Code

The TMx00 Control Software can be used for *Temp Code* and *CorrDAC Code* data collection by manually measuring the *Temp Code* and entering the *CorrDAC Code* to determine the center frequency at each desired temperature point. An automated data collection process using I²C commands is a more efficient methodology.

I²C Command Option

Measure the temperature code, *Temp Code*, after the chamber is stabilized by issuing the following command. This example assumes a delay of 100.

Send: 0x14, 0x05, 0x64, 0x83

Recv: 0x14, 0x00, 0xEC

Read the data.

Send: 0x15, 0xEB

Recv: 0x15, data_low, data_high, 0x05, Checksum

Determine the *CorrDAC Code* for Center Frequency

At each temperature point, the specific *CorrDAC Code* for the correct center frequency needs to be obtained. This is accomplished by stepping through the Correction DAC codes and measuring the resulting frequency until the appropriate *CorrDAC Code* is determined.

Step the Correction DAC code to set the oscillator to the desired center frequency through the TMx00 Control Software or by issuing the following I2C command:

Send: 0x03, 0x06, data_low, data_high, checksum

Recv: 0x03, 0x00, 0xFD

Coarse Step the Correction DAC

Stepping through all the individual Correction DAC codes measuring the frequency is a slow process. A faster approach is to first perform a coarse step sweep of the Correction DAC codes, possibly 256 codes for each step. This will provide a coarse estimate of the correct *CorrDAC Code* to match the center frequency by linear interpolating the results.

Fine Step the Correction DAC

Once an estimate of the *CorrDAC Code* is achieved, step the Correction DAC code by one count at a time around the estimated *CorrDAC Code* to determine the precise *CorrDAC Code*. A suggested range is ± 64 or 128 codes around the estimate.

Table 1 Example Temp Code & CorrDAC Code Raw Data Set

4 VOLTAGE DATA COLLECTION FLOW

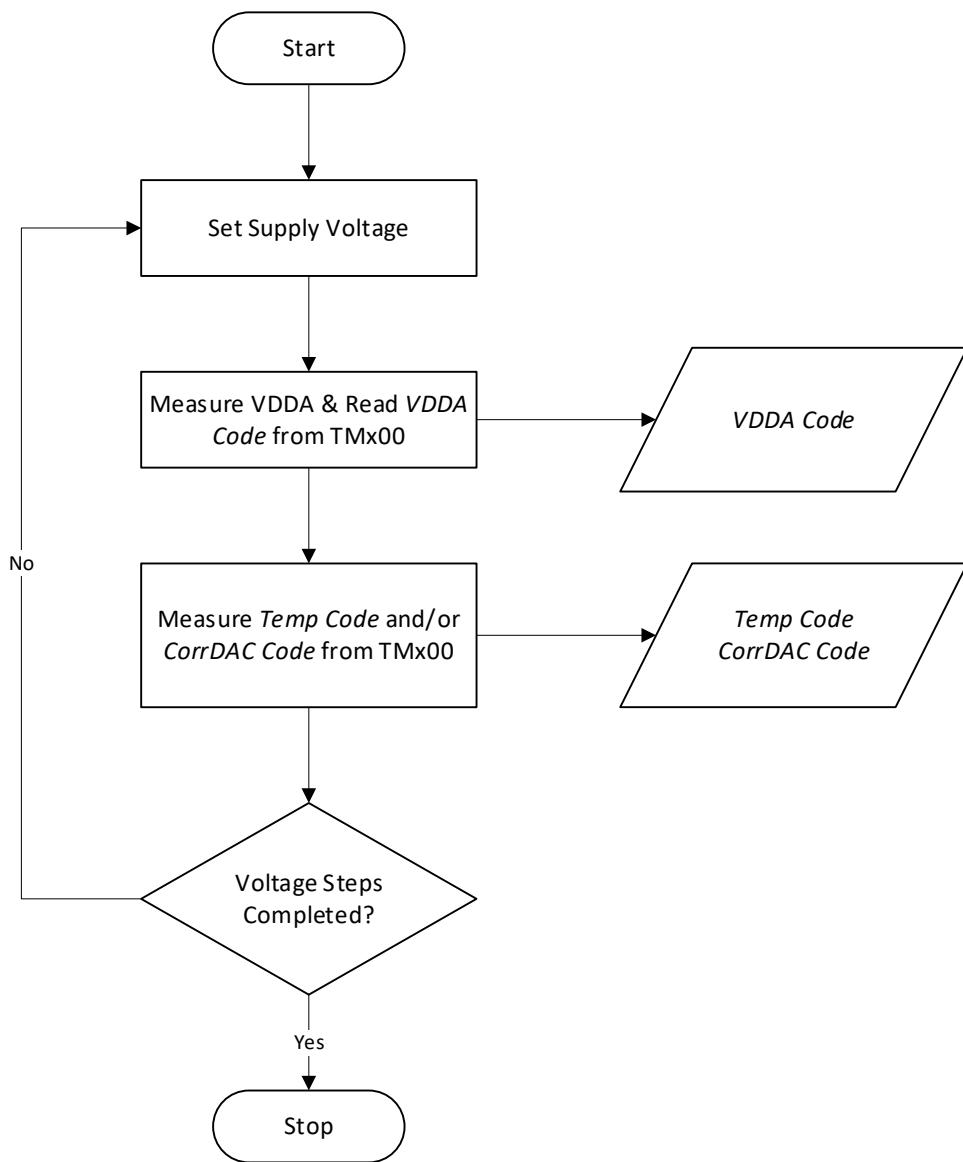

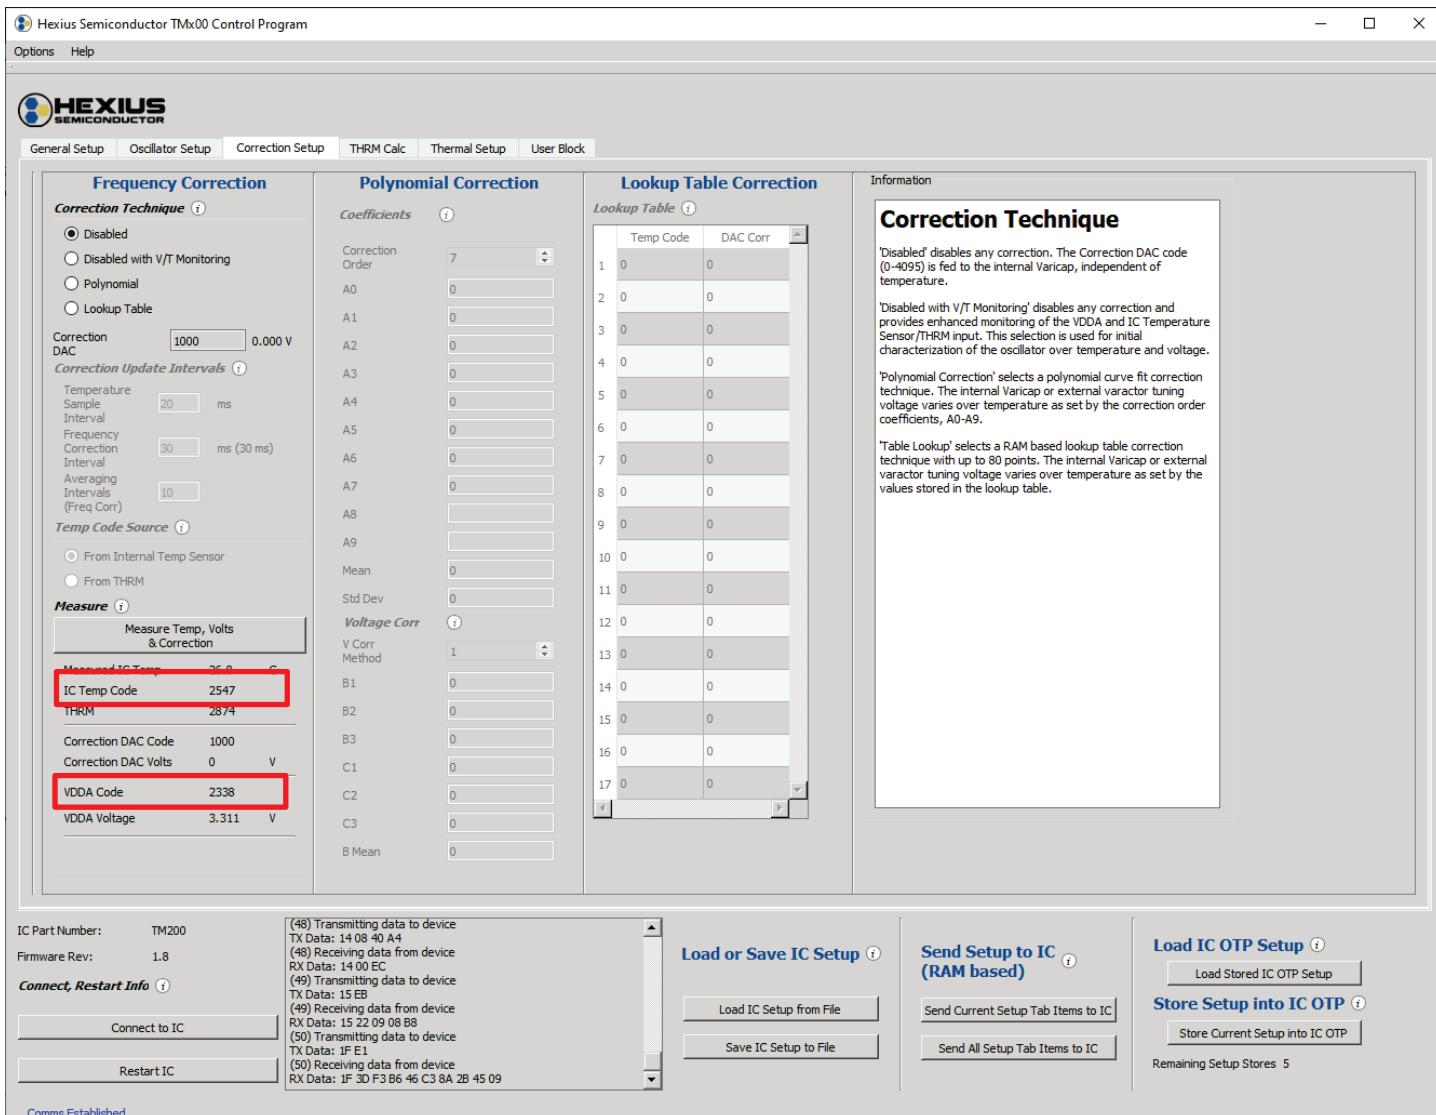

Figure 5 Voltage Data Collection Flow

Set Supply Voltage

Set the supply voltage to the desired value.

Measure Supply Voltage and Read VDDA Code

The TMx00 Control Software can be used for repeated data collection for *VDDA Code* and *Temp Code* by manually measuring the *VDDA Code* and *Temp Code* at each voltage step. An automated data collection process using I²C commands may be a more efficient methodology.

I²C Command Option

Measure the voltage code, *VDDA Code*, after the supply voltage is set to the desired value by issuing the following command. This example assumes a delay of 100.

Send: 0x14, 0x08, 0x64, 0x80

Recv: 0x14, 0x00, 0xEC

Read the data.

Send: 0x15, 0xEB

Recv: 0x15, data_low, data_high, 0x05, Checksum

Measure Temperature & Read Temp Code

At each supply voltage point, read the *Temp Code* to measure the shift.

I²C Command Option

Measure the temperature code, *Temp Code*, after the chamber is stabilized by issuing the following command. This example assumes a delay of 100.

Send: 0x14, 0x05, 0x64, 0x83

Recv: 0x14, 0x00, 0xEC

Read the data.

Send: 0x15, 0xEB

Recv: 0x15, data_low, data_high, 0x05, Checksum

5 LOOKUP TABLE IMPLEMENTATION FLOW

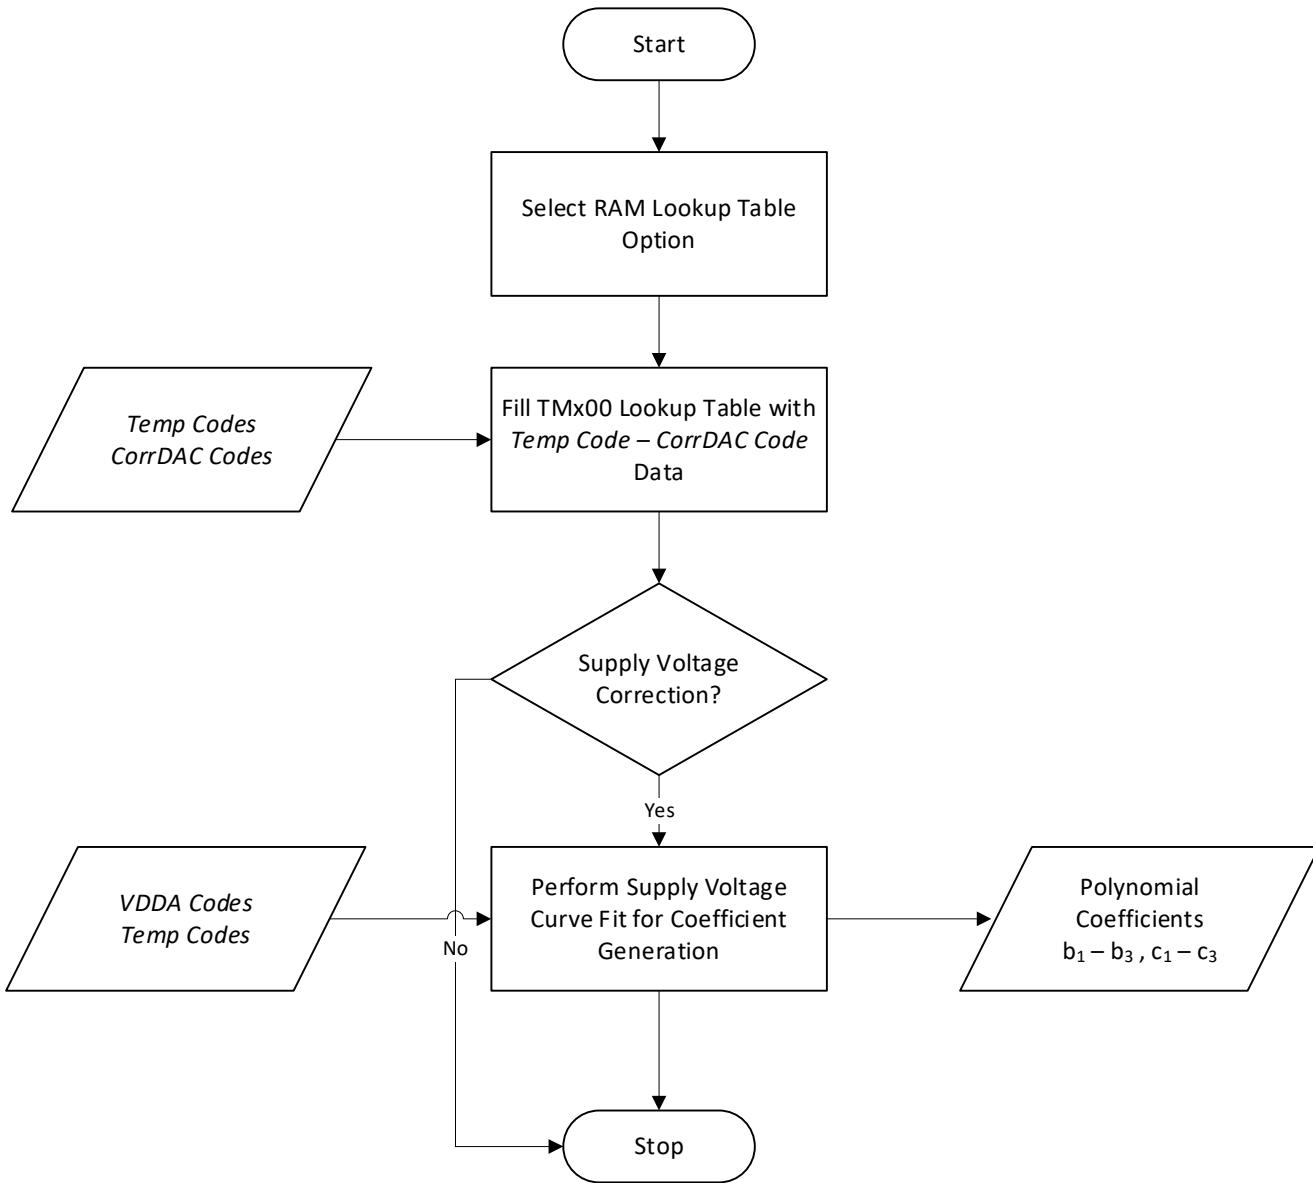

Figure 6 Lookup Table Implementation Flow

The Linear Lookup Table correction technique uses the measured reading from the IC temperature sensor or external thermistor (*Temp Code*) and generates it into a *CorrDAC Code* via a lookup table.

The lookup table is arranged from the lowest *Temp Code* to the highest *Temp Code* with up to 80 defined points. The spacing between the points is user defined to account for changing crystal temperature coefficient slopes. The appropriate DAC correction code (*CorrDAC Code*) between the defined *Temp Code* points is calculated with a linear interpolation technique.

Select Lookup Table

The Lookup Table correction algorithm in the TMx00 uses up to 80 data points of *Temp Code – CorrDAC Codes* pairings.

Information

Lookup Table

The Lookup Table Correction technique uses the measured temperature reading (Temp Code) and translates it into a Correction DAC code (CorrDAC) via a lookup table with linear interpolation. The DAC Corr value is an integer with the range of 0 to 4095 and has a corresponding voltage.

The Lookup Table is arranged from the lowest temperature to the highest temperature with up to 80 points.

Temperature readings between defined points are linear interpolated and converted in the appropriate Correction DAC code.

Temperature codes below the lowest table entry generate the lowest Correction DAC code. Temperature codes above the highest table entry generate the highest Correction DAC code.

Zero values for Temp Code and CorrDAC mark the end of the table if less than 80 elements are filled.

Voltage correction can also be used for enhanced accuracy by adjusting the lookup calculations.

Fill TMx100 Lookup Table

Fill in the Lookup Table via the TMx00 Control Software by taking the *Temp Code* and *CorrDAC Code* value gathered during the temperature data collection (Table 1) and entering it into the entry table. The lookup table data needs to be arranged from the lowest *Temp Code* to the highest *Temp Code*. The end of the table occurs when either 1) both the *Temp Code* and the *CorrDAC Code* values for an entry are zero, or 2) all table entries are filled.

If the measured *Temp Code* value is below the minimum value in the table, the *CorrDAC Code* value is set to the value that corresponds to the lowest *Temp Code* in the table. If the *Temp Code* is above the maximum value in the table, the *CorrDAC Code* value is set to the value that corresponds to the highest *Temp Code* in the table.

If the measured temperature is the exact value of a *Temp Code*, the corresponding *CorrDAC Code* value is used for the correction. For measured temperatures between the Lookup Table's *Temp Codes*, the *CorrDAC Code* values are linearly interpolated. Since the temperature coefficient curve of a crystal is non-linear, the amount and spacing of the *Temp Code* - *CorrDAC Code* entries should be optimized to minimize the correction error (Figure 7) depending on the rate of change of the temperature coefficient curve within a certain temperature range. It should be noted that the *Temp Code* values in the Lookup Table do not need to be equally spaced.

Temp Code	DAC Corr
1986	2512
2002	2426
2019	2344
2035	2271
2052	2203
2069	2143
2086	2097
2103	2047
2120	2008
2136	1977
2154	1953
2170	1935
2187	1925
2204	1921
2220	1923
2237	1931
2254	1945

The screenshot shows the TMx00 Control Program interface with the 'Lookup Table Correction' tab selected. The 'Lookup Table' section contains a table with two columns: 'Temp Code' and 'DAC Corr'. The table lists 17 rows of data, starting with Temp Code 1986 and DAC Corr 2512, and ending with Temp Code 2254 and DAC Corr 1945. A red box highlights this table. The rest of the interface includes sections for Frequency Correction, Polynomial Correction, and various setup tabs like General Setup, Oscillator Setup, and Thermal Setup.

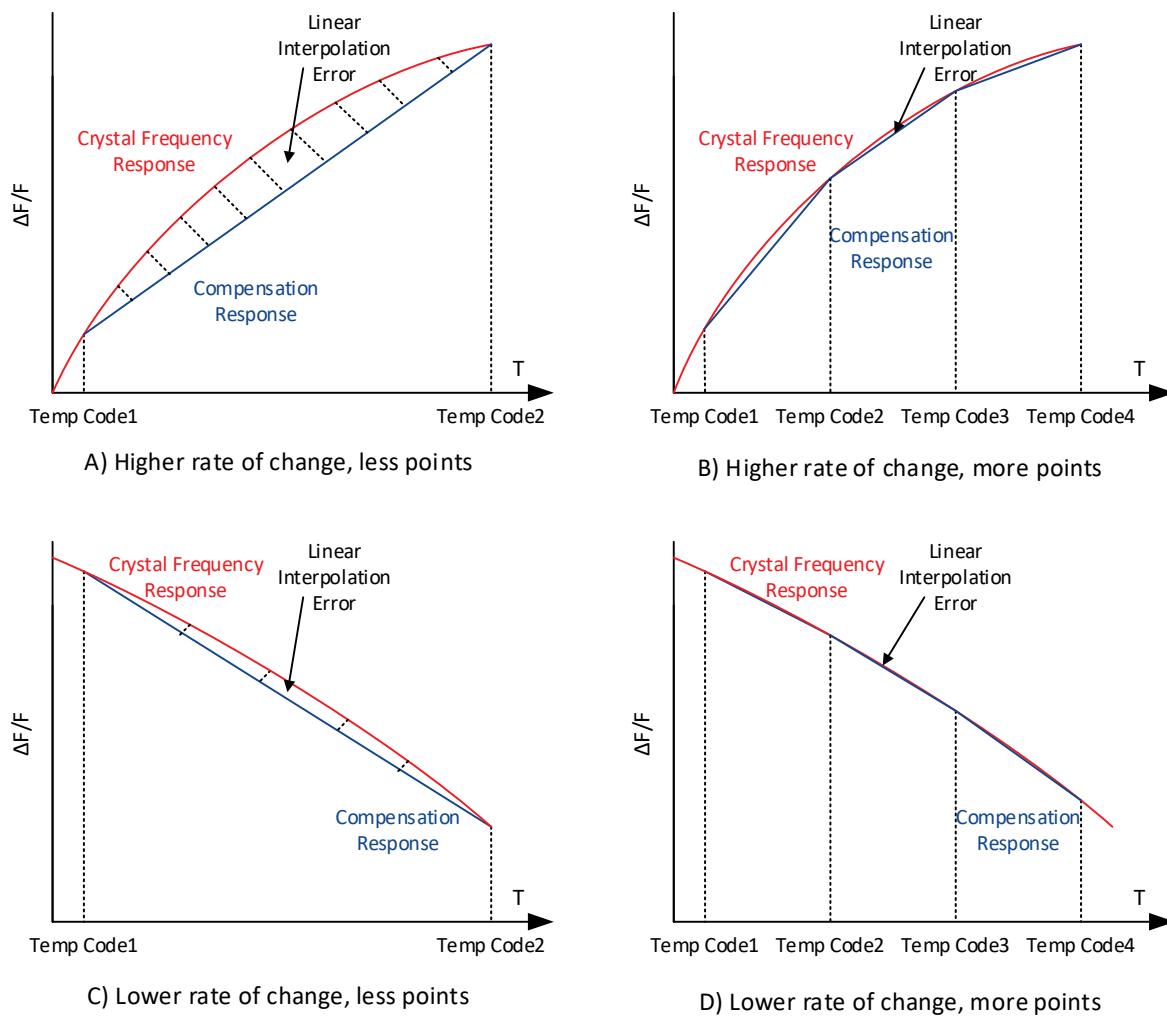

Figure 7 Linear Interpolation Temp Code Spacing Considerations

I²C Command Option

The *lookup table* variable contains up to 80 pairs of temperature code readings for the table lookup and tuning DAC code values, 3 bytes per pair.

The first 1.5 bytes in each entry contain the *Temp Code*, and the last 1.5 bytes contain the *CorrDAC Code* value. The most significant bit of the *Temp Code* is in the most significant bit of the first byte. The most significant bit of the *CorrDAC Code* starts at the most significant bit of the bottom nibble in the middle byte. The *Temp Code* readings must be monotonic from low to high. The *CorrDAC Code* values do not have that restriction.

Please reference the *TMx00 Programming Reference Manual* for more information.

Perform Supply Voltage Correction (Optional)

Using the Lookup Table for temperature correction instead of the polynomial correction does not limit the user from the Supply Voltage Correction. The Supply Voltage Correction flow is described in section 7.

6 TEMPERATURE POLYNOMIAL IMPLEMENTATION FLOW

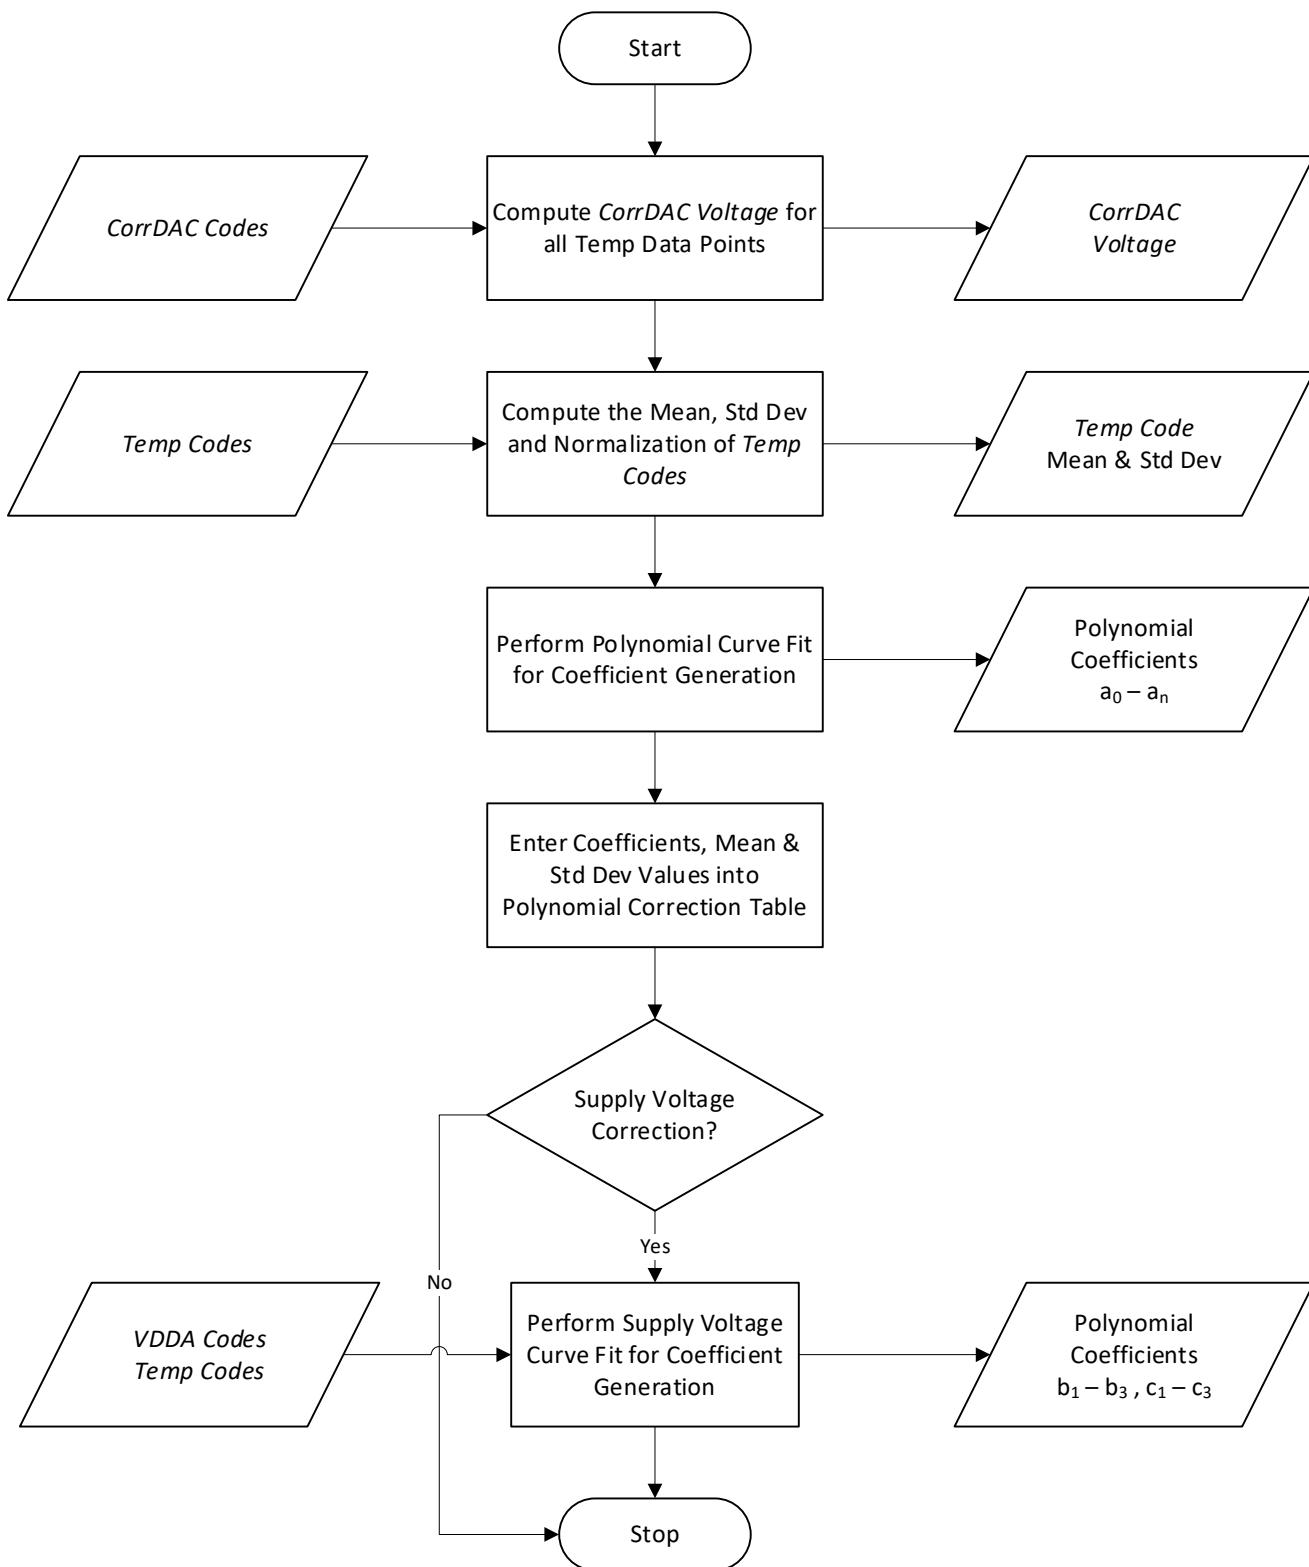

Figure 8 Temperature Polynomial Implementation Flow

Compute the *CorrDAC Voltages* for all Temperature Points

Using the *Temp Code* and *CorrDAC Code* raw data, calculate the *CorrDAC Voltage* for each temperature point. The polynomial curve fit calculation requires the *CorrDAC Voltage* and not the *CorrDAC Code* (Lookup Table technique).

The *CorrDAC Voltage* is the resulting Correction DAC output voltage for a given *CorrDAC Code*. It is calculated by multiplying the Correction DAC's reference voltage by the ratio of the *CorrDAC Code* to the Correction DAC's full-scale code (4095).

$$\text{CorrDAC Voltage} = \frac{\text{CorrDAC Code}}{4095} * \text{BYPASS pin Voltage}$$

Example:

Table 3 CorrDAC Voltage Calculation Example

Temperature (C)	Temp Code	CorrDAC Code	CorrDAC Voltage
-40	2005	2720	1.92625153

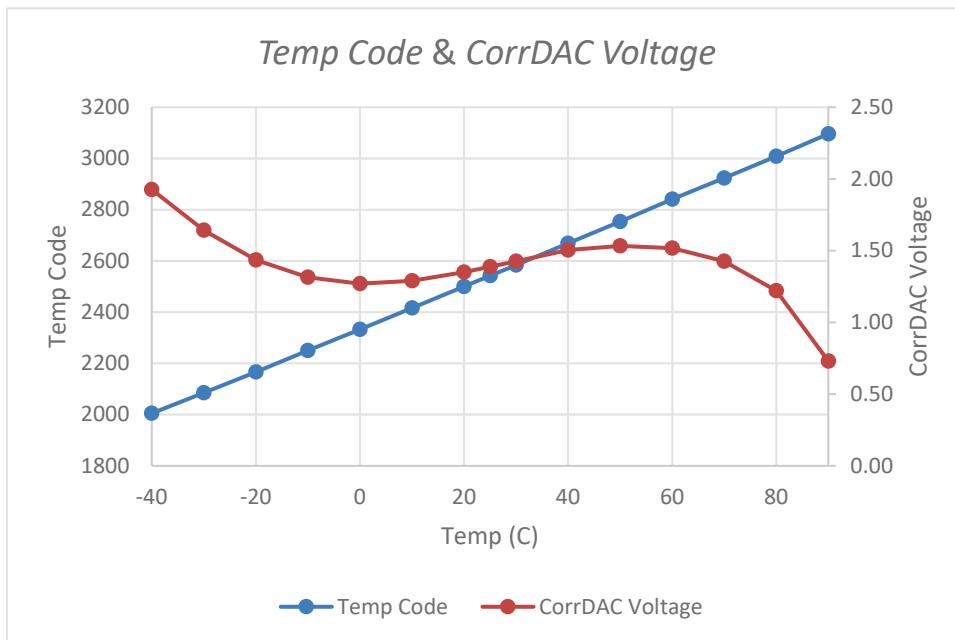

Figure 9 Temp Code & CorrDAC Voltage Over Temperature Sweep

Compute the Mean, Std Dev, and Normalization of *Temp Codes*

Processing the *Temp Code* data for mean and standard deviation may enhance the accuracy of the correction equations. The result is the *Normalized Temp Code*.

Using the Table 3 *Temp Code* values, the mean is:

$$\text{sample}_i = \text{each sample}$$

$$N = \text{number of samples}$$

$$\text{Mean} = \frac{\sum(\text{sample}_i)}{N} = 2544.9333$$

Using the Table 3 *Temp Code* values, the standard deviation is

$$\sigma = \sqrt{\frac{\sum(\text{sample}_i - \text{mean})^2}{N}}$$

$$\sigma = 327.2820$$

Normalized *Temp Code* values are computed by:

$$\text{Normalized Temp Code} = \frac{\text{Temperature Code} - \text{Mean}}{\sigma}$$

Table 4 Example with Normalized Temperature Code

Perform Temperature Correction Polynomial Curve Fit for Coefficient Generation

The general form of the polynomial correction equation is:

$$\text{Corr}_{\text{temp}}(x) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 + a_9x^9$$

x = Normalize Temp Code: TempCode normalized for Mean and Standard Deviation

$\text{Corr}_{\text{temp}}(x)$ = Correction DAC output voltage

Assuming 7th order correction, the equation is:

$$\text{Corr}_{\text{temp}}(x) = a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7$$

The term x is the *Normalized Temp Code*, and $\text{Corr}_{\text{temp}}(x)$ is the Correction DAC voltage output.

Table 5 Data Values Entered Into Polynomial Curve Fit Calculation

x	$\text{Corr}_{\text{temp}}(x)$
-1.649749389	1.92625153
-1.405311895	1.64156288
-1.154763463	1.43619048
-0.901159562	1.31438339
-0.647555662	1.27047619
-0.393951762	1.29030525
-0.137292393	1.34979243
-0.008962708	1.38874237
0.119366976	1.42627595
0.379081814	1.50417582
0.638796652	1.53250305
0.904622427	1.51692308
1.155170859	1.42698413
1.417941165	1.22019536
1.68376694	0.73084249

If the *Normalized Temp Code* and *CorrDAC Voltage* values are inputted into a polynomial curve fit calculator (MATLAB, Stats.blue, etc), the following coefficients are generated:

Table 6 Temperature Correction Polynomial Coefficients

Coefficient	Estimate	Standard Error
a_0	1.3932454	0.00185
a_1	0.3157902	0.00672
a_2	0.0033945	0.00818
a_3	-0.2853885	0.0168
a_4	0.0445517	0.00771
a_5	0.0517127	0.01191
a_6	-0.0178741	0.00186
a_7	-0.0128117	0.00245

The polynomial correction equation then becomes:

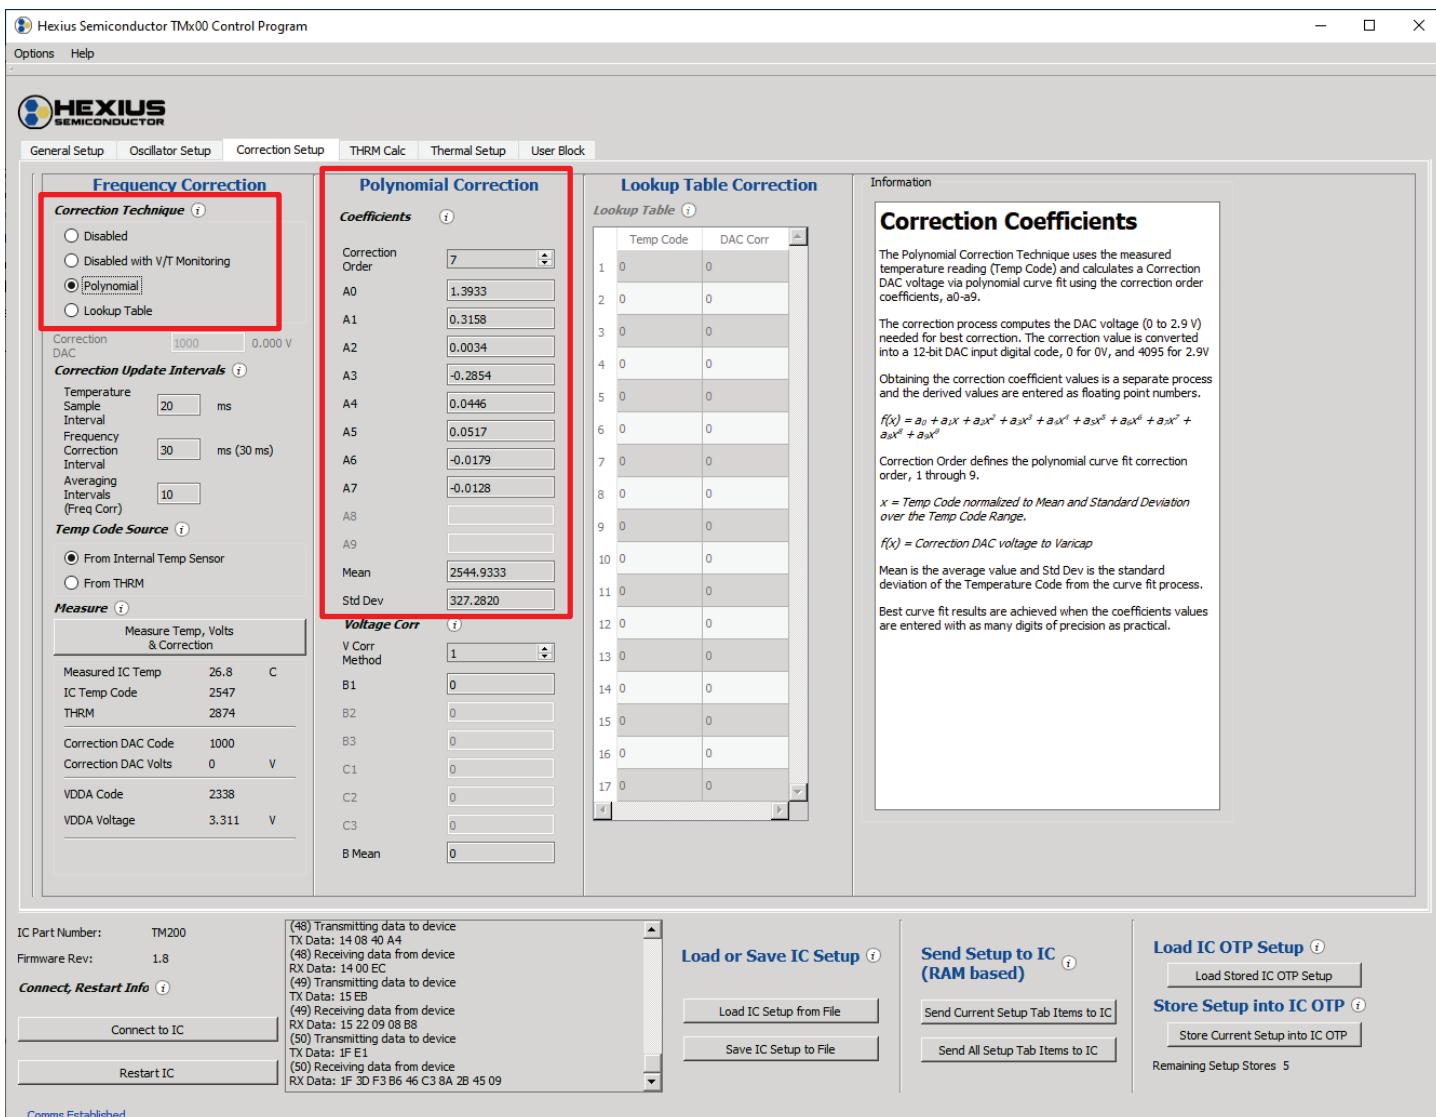

$$\text{Corr}_{\text{temp}}(x) = 1.3933 + 0.3158x + 0.0034x^2 - 0.2854x^3 + 0.0446x^4 + 0.0517x^5 - 0.0179x^6 - 0.0128x^7$$

The numeric values shown in this example are illustrated with limited digits of precision. All significant digits should be maintained through the curve fitting process.

The TMx00 firmware automatically converts the DAC voltage computed by the equation into the needed DAC code for setting the desired frequency.

Enter Coefficients, Mean, & Standard Deviation Values

Select the Polynomial Correction technique and set the Correction Order. Enter the coefficient values a_0 – a_9 , mean, and standard deviation calculated into the TMx00 Control Software Polynomial Correction Table.

I²C Command Option

The resultant terms are stored in the setup block, each as a single precision floating point value. a_0 is stored in *corr_a0*, a_1 is stored in *corr_a1*, up through the correction order specified. The mean (2544.9333) is stored in *corr_mean*, and the standard deviation (327.2820) is stored in *corr_std*.

7 SUPPLY VOLTAGE IMPLEMENTATION FLOW

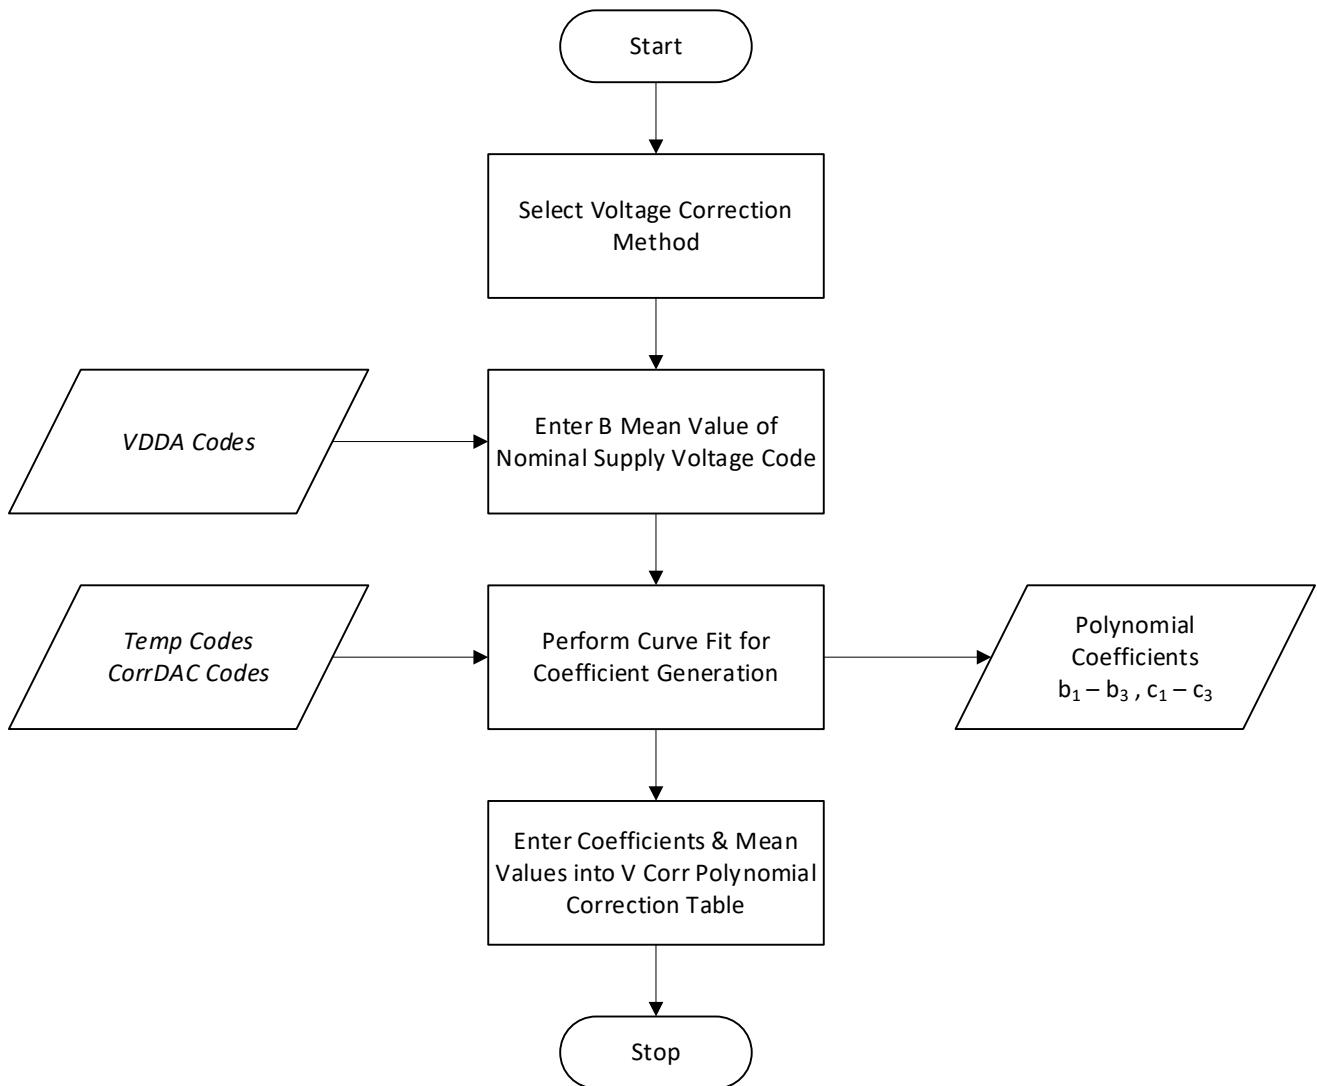

Figure 10 Supply Voltage Polynomial Implementation Flow

The *CorrDAC Voltage* values are not overly sensitive to supply voltage (VDDA) variation, but the *Temp Code Normalized* values have a small dependency on supply voltage. This means that supply voltage variations will shift the *Temp Code* values. The supply voltage polynomial curve fit correction techniques are optional enhanced correction methods that generate adjustment terms to account for this shift.

A *Corr_{voltage}* term corrects for frequency shifts over supply voltage variation and uses the coefficients, $b_1 - b_3$. (Most common since the supply voltage variations will shift the Temp Code values with a linear relationship.)

A *Corr_{voltage_temp}* term corrects for frequency shifts from cross correlated supply voltage and temperature variation and uses the coefficients, $c_1 - c_3$. (Applicable to very high stability requirements)

The user selects whether these correction terms are applied to either the *Temp Code* or *CorrDAC Code* depending on the architecture and sensitivity of supply voltage movement of the module. *Temp Code* or *CorrDAC* adjustments each have further options regarding the order of correction desired.

Temp Code Adjustment Option

Applying the correction by adjusting the *Temp Code* is defined as

$$Temp_{ADJ} = TempCodeNormalized + \Delta TempCode(\Delta VDDA)$$

Where:

$Temp_{ADJ}$ is the new value input into the main $Corr_{temp}(x)$ function for frequency correction

$\Delta TempCode$ is the TempCode adjustment based on voltage and temperature measurements

$\Delta VDDA$ is the VDDA Code normalized to the Mean and Standard Deviation

Temp Code Corr_{voltage} 1st Order Correction Option – MOST COMMON

$$\Delta TempCode(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA)$$

Temp Code Corr_{voltage} 3rd Order Correction Option

$$\Delta TempCode(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3$$

Temp Code Corr_{voltage} & Corr_{voltage temp} 3rd Order Correction Option

$$\begin{aligned} \Delta TempCode(\Delta VDDA) &= Corr_{voltage}(\Delta VDDA) + Corr_{voltage_temp}(\Delta VDDA) \\ &= b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3 + c_1(\Delta VDDA)(TempCode) \\ &\quad + c_2(\Delta VDDA)^2(TempCode) + c_3(\Delta VDDA)(TempCode)^2 \end{aligned}$$

CorrDAC Code Adjustment Option

Applying the correction by adjusting the *CorrDAC Code* is defined as

$$CorrDAC_{ADJ} Code = CorrDAC Code + \Delta CorrDAC Code(\Delta VDDA) \text{ (when using the Lookup Table Correction)}$$

Or

$$CorrDAC_{ADJ} Voltage = CorrDAC Voltage + \Delta CorrDAC Voltage(\Delta VDDA) \text{ (when using the Polynomial Correction)}$$

Where:

$CorrDAC_{ADJ} Code$ is the new *CorrDAC Code* value output for frequency correction (Lookup Table Correction)

$CorrDAC_{ADJ} Voltage$ is the new *CorrDAC Voltage* output for frequency correction (Polynomial Correction)

$\Delta CorrDAC$ is the *CorrDAC Code/Voltage* adjustment based on voltage and temperature measurements.

$\Delta VDDA$ is the VDDA Code normalized to the Mean and Standard Deviation.

CorrDAC Code Corr_{voltage} 1st Order Correction Option - MOST COMMON

$$\Delta CorrDAC Code(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA)$$

CorrDAC Code Corr_{voltage} 3rd Order Correction Option

$$\Delta CorrDAC Code(\Delta VDDA) = Corr_{voltage}(\Delta VDDA) = b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3$$

CorrDAC Code Corr_{voltage} & Corr_{voltage temp} 3rd Order Correction Option

$$\begin{aligned} \Delta CorrDAC Code(\Delta VDDA) &= Corr_{voltage}(\Delta VDDA) + Corr_{voltage_temp}(\Delta VDDA) \\ &= b_1(\Delta VDDA) + b_2(\Delta VDDA)^2 + b_3(\Delta VDDA)^3 + c_1(\Delta VDDA)(TempCode) \\ &\quad + c_2(\Delta VDDA)^2(TempCode) + c_3(\Delta VDDA)(TempCode)^2 \end{aligned}$$

The measured VDDA voltage is one-half of the VDDA value, or a nominal code of 2330 (0x091A) for a 3.3V VDDA value. The VDDA voltage is varied across the supply range, and the resulting temperature code is measured at a single temperature value.

Temp Code Adjustment Example - Linear Correction

The data below is from a supply voltage sweep that collects the *VDDA Code* and *Temp Code* information needed for a correction implementation. This example assumes the Δ frequency over Δ VDDA is only caused by *Temp Code* shifts.

Table 7 Voltage Correction Temp Code Data Set Example

Supply (V)	VDDA Code	Temp Code
3.135	2213	2542
3.2175	2272	2544
3.3	2330	2546
3.3825	2388	2548
3.465	2446	2550

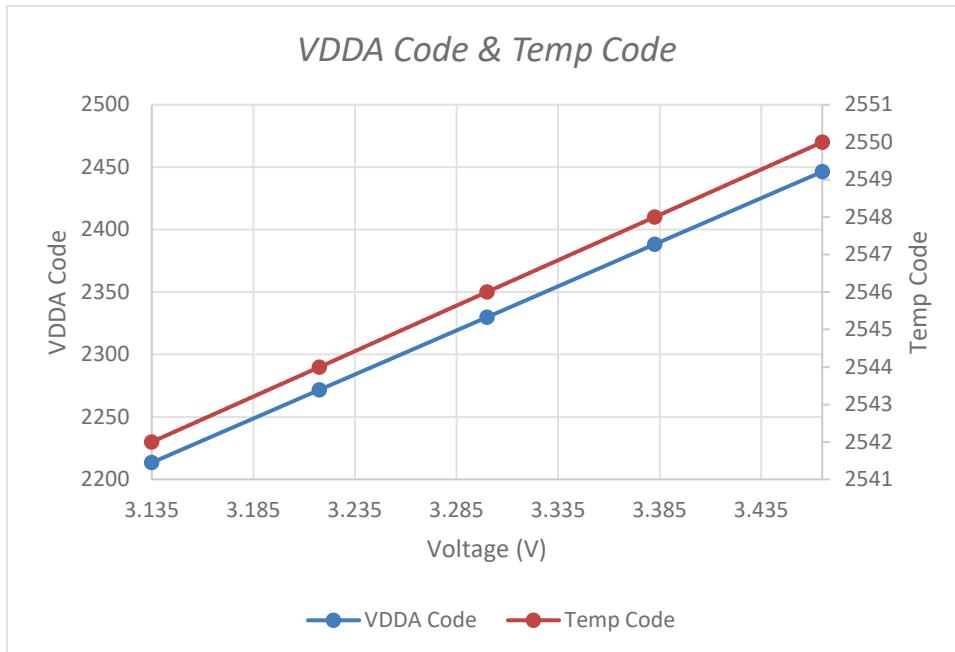

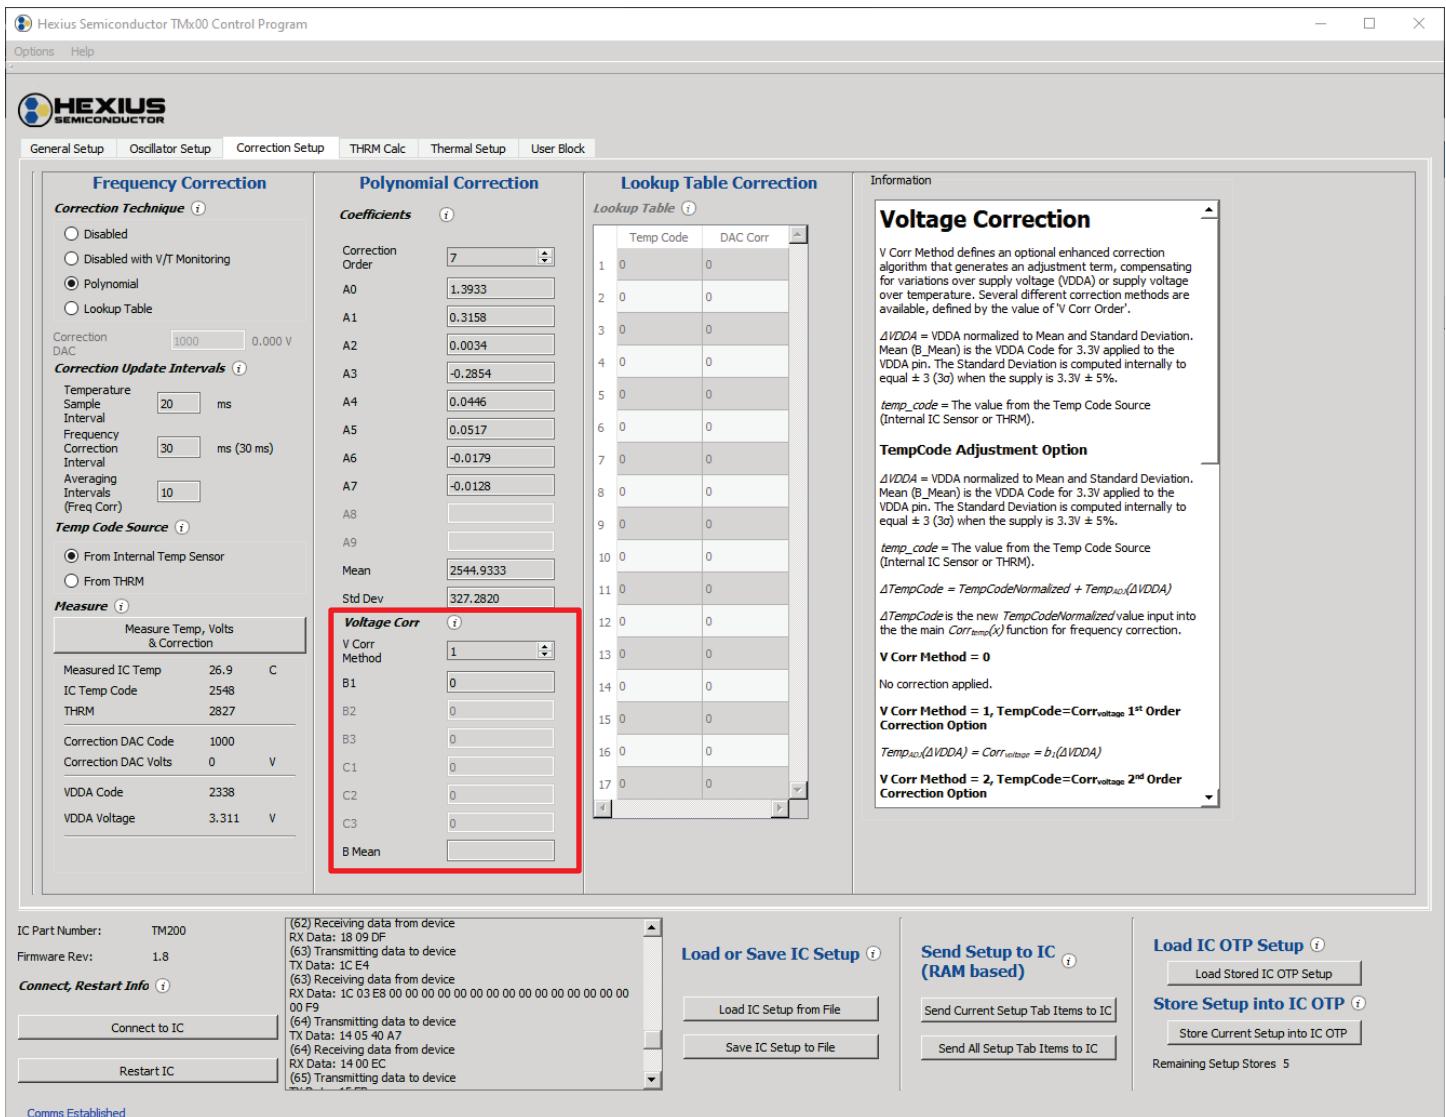

Figure 11 VDDA Code & Temp Voltage Over Supply Voltage Sweep

The relationship between *VDDA Code* and *Temp Code* is linear. Therefore, select V Corr Method 1 which is:

Temp Code Corr_{voltage} 1st Order Correction Option

$$\Delta \text{TempCode} (\Delta \text{VDDA}) = \text{Corr}_{\text{voltage}} (\Delta \text{VDDA}) = b_1 (\Delta \text{VDDA})$$

For this correction technique, the B Mean and B1 terms need to be entered.

The B Mean term is the nominal *VDDA Code* value when 3.3V is applied to VDDA:

$$VDDACode_{Nom} = VDDA Code measured by IC when 3.3 V is applied to VDDA$$

In this example, that value is 2330.

Because the supply voltage range of the TMx00 is specified at $\pm 5\%$, the standard deviation of the *VDDA Code* range is set internally with respect to the nominal *VDDA Code*.

$$VDDA_{SD} = \text{Standard deviation of } VDDA$$

The Standard Deviation is defined so a 5% high supply voltage gives a $VDDA_{SD}$ (or σ) of +3.0, and a 5% low supply gives a $VDDA_{SD}$ of -3.0.

$$VDDA_{SD} = VDDACode_{NOM} \left(\frac{0.05}{3} \right)$$

$VDDACode_{NOM}$ is the ADC code value measured by the IC when the VDDA supply voltage is 3.3V. A typical ADC code value is 2330. Note that the VDDA ADC input is divided by 2, so the 2330 code represents an input value of 1.65V.

$$\Delta_{VDDA} = \frac{VDDACode_{Meas} - VDDACode_{Nom}}{VDDA_{SD}}$$

$VDDA_{SD}$ = Standard deviation of VDDA set so that ± 0.05 wrt $VDDACode_{3.3V}$ produces a σ of ± 3

$$VDDA_{SD} = VDDACode_{NOM} \left(\frac{0.05}{3} \right)$$

$$\Delta_{VDDA} = \frac{VDDACode_{Meas} - VDDACode_{Nom}}{VDDA_{SD}}$$

If the frequency variation is mostly caused by the variation in temperature sensor reading, the B1 term input should be set to the inverse of the *Temp Code* slope:

$$B1 = -\frac{1}{m}$$

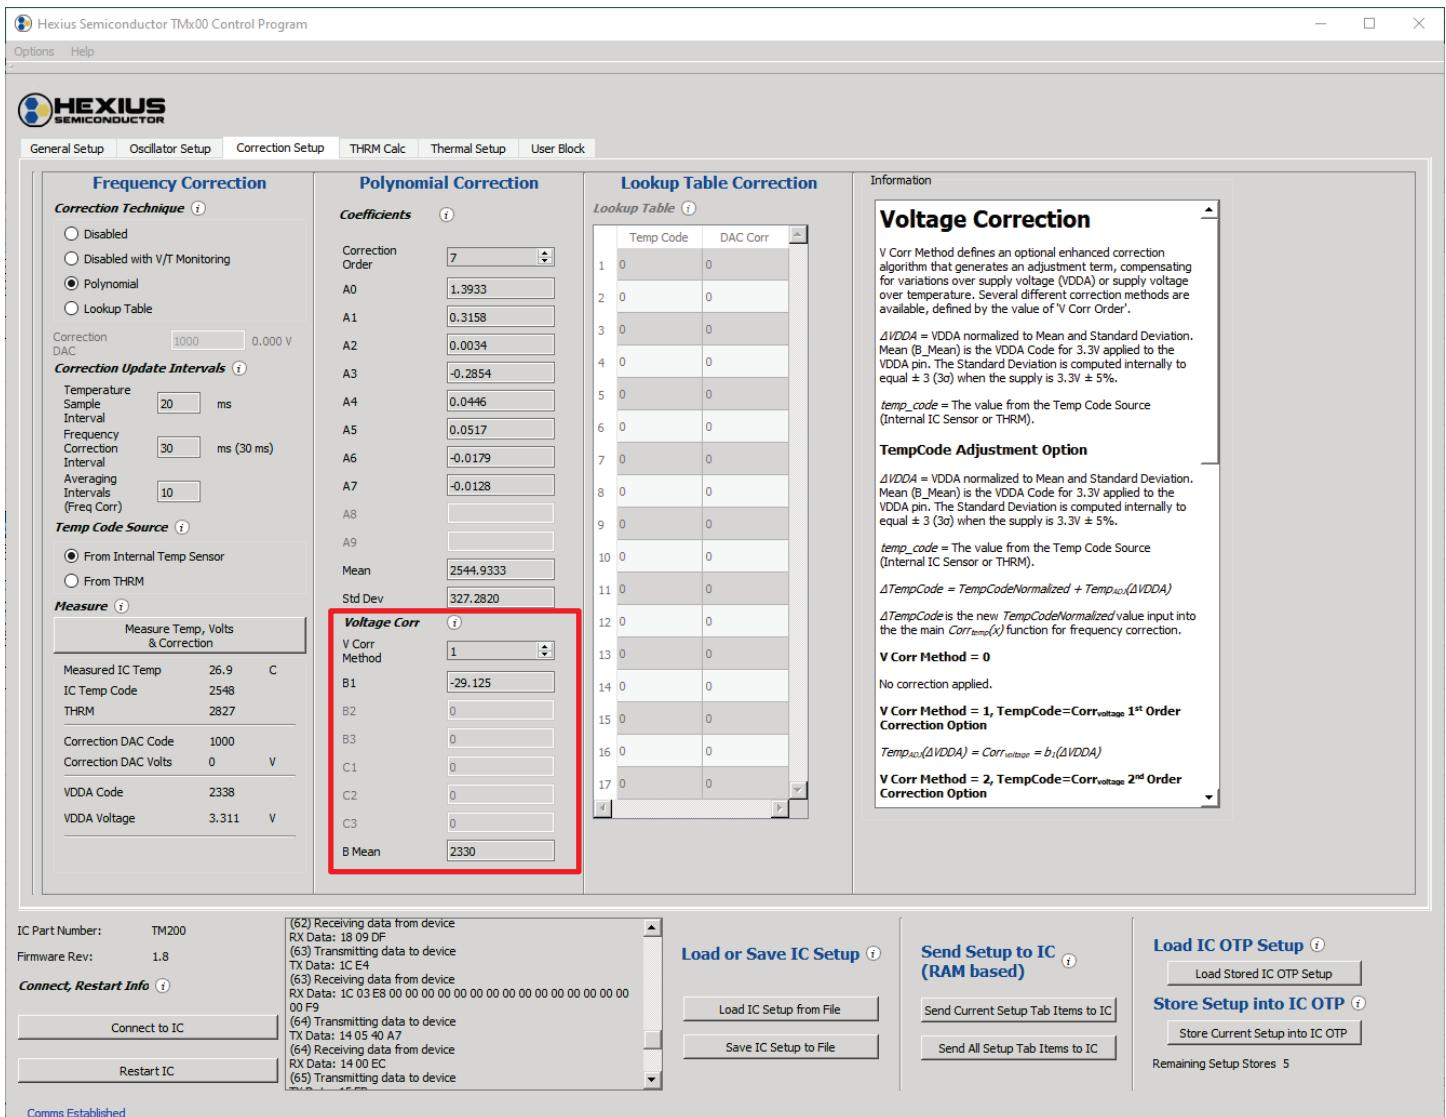

$$m = \frac{(TempCode_2 - TempCode_1)}{(VDDACode_2 - VDDACode_1)}$$

For this example:

$$m = \frac{(2550 - 2542)}{(2446 - 2213)} = 0.034335$$

$$B1 = -\frac{1}{m} = -\frac{1}{0.034335} = -29.125$$

If the frequency variation consists of terms dependent on the temperature sensor and the VDDA supply voltage, then the B1 should be chosen so that the frequency slope is minimized over the supply voltage range. For example, this method of adjustment would be needed for applications in which BYPASS and VDDA are connected. The DAC output voltage changes with the BYPASS value so the needed tuning command voltage would also change.

The TMx00 will calculate all the necessary normalization values to generate and apply the *Temp Code* adjustment term

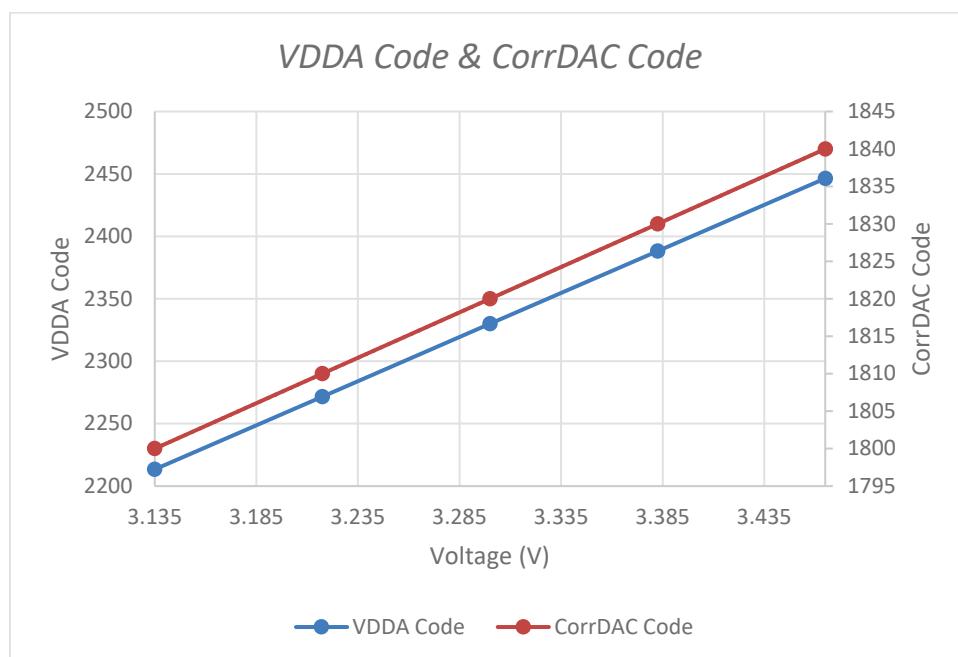

$$\Delta \text{TempCode} (\Delta VDDA) = \text{Corr}_{\text{voltage}} (\Delta VDDA) = b_1 (\Delta VDDA)$$

CorrDAC Code Adjustment Example - Linear Correction

The CorrDAC Code adjustment is identical to the Temp Code adjustment but uses *CorrDAC Codes* instead of *Temp Codes*. If the frequency output shift of the module is not solely dependent on *Temp Code* shifts, the collected data be changed to the *VDDA Code* and *CorrDAC Code* for a correction implementation. This implementation may be a good technique if the BYPASS voltage is tied to VDDA which will cause a shift in the internal Varicap (if used). The data below is from a supply voltage sweep that collects the *VDDA Code* and *CorrDAC Code* information needed for a correction implementation.

Table 8 Voltage Correction CorrDAC Code Data Set Example

Supply (V)	VDDA Code	CorrDAC Code
3.135	2213	1816
3.2175	2272	1818
3.30	2330	1820
3.3825	2388	1822
3.465	2446	1824

The relationship between *VDDA Code* and *CorrDAC Code* is linear. Therefore, select V Corr Method 5 which is:

CorrDAC Code $\text{Corr}_{\text{voltage}} \cdot 1^{\text{st}}$ Order Correction Option

$$\Delta \text{CorrDAC Code}(\Delta \text{VDDA}) = \text{Corr}_{\text{voltage}}(\Delta \text{VDDA}) = b_1(\Delta \text{VDDA})$$

B Mean is 2330

The B1 term input needs to be inverse of the *CorrDAC Code* slope:

$$B1 = -\frac{1}{m}$$

$$m = \frac{(\text{CorrDAC Code}_2 - \text{CorrDAC Code}_1)}{(\text{VDDA Code}_2 - \text{VDDA Code}_1)}$$

For this example:

$$m = \frac{(1840 - 1800)}{(2446 - 2213)} = 0.171674$$

$$B1 = -\frac{1}{m} = -\frac{1}{0.171674} = -5.825$$

The screenshot shows the Hexius Semiconductor TMx00 Control Program interface. The 'Correction Setup' tab is active. In the 'Voltage Corr' section, the 'V Corr Method' dropdown is set to 5, and the 'B1' field contains the value -5.825. The 'B Mean' field contains the value 2330. A red box highlights this section. The 'Information' panel on the right explains the formula for V Corr Method 5: $\Delta \text{CorrDAC Code} = \text{CorrDAC Code} + \text{CorrDAC}_{\text{AD}}(\Delta \text{VDDA})$ (lookup table correction). It also shows the formula for CorrDAC Voltage: $\Delta \text{CorrDAC Voltage} = \text{CorrDAC Voltage} + \text{CorrDAC}_{\text{AD}}(\Delta \text{VDDA})$ (polynomial correction). The 'Information' panel continues with details about CorrDAC_{AD} and V Corr Method 4, 6, and 7.
